Each stem must be expanded gradually, first with a $\frac{1}{2} \mathrm{in}$. cone punch, which should be lightly hammered to avoid crushing the stem, then a larger cone punch is used and the stem expanded to its full extent, after which it is riveted over on to the washer. It is often advisable to use three or even four sizes of cone punches in order to expand the metal without fracture. The margin and eyelets to be riveted should rest on a block of wood during the process. An eyelet and washer, and a sectional diagram illustrating how they are fitted, are shown at A and B respectively, in Fig. 19. A special punch set can be procured for this purpose.
After the practice acquired in fitting 2 or 3 eyelets, rapid progress will be made with the remainder. Eleven $\frac{3}{8}$ in. eyelets are riveted in the right side sheet, $\mathbf{E}$, as follows: A space of 3 in . in from the left side is first marked off, then a parallel line is drawn through the point, across the width of the sheet. The points at which the eyelets are to be inserted are marked off on the parallel line, from the measurements given in Fig. 17, then holes are cut and the eyelets fitted and secured in place as previously described. Eleven $\frac{3}{8} \mathrm{in}$. eyelets are fitted in the left side sheet, $\stackrel{F}{5}$, a parallel line 3 in . from the right side being drawn and the positions of the holes marked on it, their spacing being the same as those in shect E .

The next step is to place the right side of the door-flap so that it overlaps the left side of the right side sheet for $33^{3}$ in., then the upper margin of the flap and the upper margin of the sheet are sewn together where they overlap. The left side of the flap is placed on the right side of the left side sheet and overlapped for $3 \frac{3}{4}$ in., then the upper margin of the flap is sewn to the upper margin of the sheet, as before. After the door flap has been sewn in position, the width of the door opening should be $2 \mathrm{ft} .4 \frac{1}{2} \mathrm{in}$., which space, added to the 5 ft . length of each of the side sheets $E$ and $F$, makes the total length of the front of the tent $12 \mathrm{ft} .4 \frac{1}{2} \mathrm{in}$.

The diagonal margins on the right gable sheet, $B$, are folded double, turned inward, and then sewn to the under side of the right side of the roof sheet, as shown in diagram D , Fig. 15, the inner line of each margin being sewn to the line previously marked off $3 \frac{3}{4} \mathrm{in}$. from the right side of the roof shect. The upper margin of the side sheet, D , is folded double, turned inward, and sewn to the under side of the roof sheet, as shown in diagram E, Fig 15, the inner line of the margin being sewn to the line marked off 4 in . from the upper side of the roof sheet.

The upper margins of the side sheets E and $F$, and the door flap $G$, are folded double, turned inward, and sewn to the underside of the roof sheet, the inner lines of the margins being sewn to the line marked off 4 in . from the lower side of the roof sheet. A $\frac{1}{2}$ in. ryelet is now riveted in the upper and lower sides of the roof sheet at each of the points shown in Fig. 20. The diagonal margins on the left gable shect C are folded double, turned inward, and sewn to the underside of the roof sheet, in the same manner as the margins of the right gable sheet.
The sewing having been completed, the ercction of the tent may now be proceeded with. The ground plan of the tent is first marked out on the site. and a hole 18 in. deep is made at- each of the points detailed in Fig. 21 . The holes are formed by driving
the 3 ft . long by 1 in . diameter iron pipe into
the ground by means of a heavv hammer or mau!. (The arrangement of the framework members is shown in Fig. 3.) The ridge tube $L$ is now screwed into the T's on the gable tubes H ,'then the canvas is folded and stretched flat on the ground, as shown in Fig. 22.

The 3 tubes are next placed inside the canvas, then the lower end of each gable tube is laid at the hole prepared for it in the ground. Two 14 ft . !engths of $\frac{3}{8} \mathrm{in}$. hemp rope arc attached to the shackle in each T, then the gable tubes are raised, simultancously, by two men and erccled in the holes. After the gable tubes have been brought perpendicular, the roof sheet is adjusted centrally on the ridge tube, then the side sheets are raised and the tubes P fixed in position in the holes prepared for them. The cyelets in the roof sheet arc placed on the small projecting tubes in the upper ends of the tubes $P$, then the side sheets are lowered.

## Process of Erecting the Tent

The 12 tubes, $S$, are now driven into the ground at the points shown in Fig. 3. Each tube should be about 4 ft .6 in . from the tent, and driven in a sloping direction into the ground. Twelve 8 ft . lengths are cut from the $\frac{3}{8} \mathrm{in}$. hemp rope, to form the guys, $V$, then a toggle is fitted to each length, as shown in Fig. 23. A firm knot is made on one end of each rope, then a small loop is formed on the other. These loops are placed on the small tubes where they project through the eyelets in the roof sheet. The toggles are adjusted, and the large loops of the ropes placed over the ground tubes, $S$. A toggle is fitted to each of the ropes previously attached to the shackles in the T's on the gable tubes. The ends of the ropes are knotted, and the toggles adjusted to form the ropes into loops, which are placed on their respective ground tubes, as shown in Fig. 2.

The next step is to tighten up all the guy ropes until the canvas is stretched taut. Two 5 ft . lengths are cut from the $\frac{3}{8} \mathrm{in}$. rope, then one end of a length is inserted into the upper eyelet in the side sheet $E$, and sccured.

Terrace. Paved and stepped terrace with its gay Hower beds and topiary trees, which forms a charming trangition between housc and lawn

Humpliren \& Vera Joel

with a knot. Onc end of the other length is sceured in the upper cyelet in the side sheet F . Thesc ropes serve to lace up the door flap when required, both ropes leing rove through the eyclets as shown in Fig. 24. After finishing the lacing, the lower end of each rope is secured by a $k$ not made inside the tent. which is now complete.
To dismantle the tent is an casy matter. The guy ropes are first loosened and remored from the ground tulies. The side shects are then raised and the tubes indicated at $P$ in lig. 3 are pulled up. Two men next withdraw the gable tubes and lower them to the ground, where they are removed from the canvas and the ridge tube unscrewed.
When choosing a site on which to erce the tent, a place where the ground is level dry. and sheltered should be selected, and it therc are any olstructions, such as stones, roots, etc., they should be removed before marking out the ground plan. After erecting the tent, a shallow runnel must be rug in the ground, at the gables and sides, and connceted to drain away rainwater.

During wet weather the guy ropes should be kept slach, as rain causes both them and the canvas to shrink. T'lis precaution should sot be neglected, as the shirininge of the tight guy ropes may strain the roof sheet so greatly list it may cause it to split or tear apart al the seams.
Legal Points. In some districts there are by-laws compelling holiday makers and others who live in camps or caravans for more than three days to provide for a proper water supply, samitation, and other matters nffecting health and cleanliness. These by-laws are not in tended to apply to campe conducted for boy scout and similar organizations. See Trespass.

TEREBENE. Obtained by distilling a mixture of oil of turpentine and sulphuric acid, terehene is a colourless fluid withan aromatic odour. It is a powerful antiseptic, disinfectant. and deodoriser. Terchenc has been used with much success in the treatment of chronic bronchitis. It may be given interrially, as an ingredient of cough mixture, or as an inhal ation. It is also a good intestinal disinfectant.

## TERRACE: In

 Gardens. A paved bricked or tiled terrace at the back of the house is a practical and ornamental feature. Where there is no loggin veranda or summer house such a terrace provides the basis for n garden room, easily made with the help of an awning carried down at the sides to form a screen against cold winds Garden furniture which can be casily moved adds to the attractiveness of the scheme.Where there are somewhat larger grounds a paved or brick terrace makes a delightful transition between house and garden and affords scope for some formal garden ing items, such as plants in tubs or vases, an ornamental seat and a lavender hedge. A charming paved and stepped terrace of this type is here illustrated with low l,rick walls, topiary trees and encroaching clumps of llowers.
The banks and slopes in a garden of suitable extent may be arrangerl to form terraces of grass, with berls of cultivated plants and lulbs. The incline should not exceed $45^{\circ}$, otherwise the making of beds, stepping, and trimming of grass will be a diflicult matter, whilst water will quickly run away, to the detriment of plant roots.

Soil preparation, levelling, and turfing shoukd be completed and left to settle clown before planting leegins. The surface should be a good even depth of sound loam, otherwise

Terra Cotta. Fig. 1. Persian jar in glazed terra cotta, with fantastic paintings in black, It prodauly uates
there is the risk of hot weather cracking shallow soil, and grass perishing in consequence. Turves should be cut in thick squares, kept flat, and laid from the bottom to the top of the terrace, keeping in place with pegs if necessary. After making them firm with a turfbeater, fill up the spaces with dry powdered clay, and brush the whole with a very still brush or besom.
Shrubs, roses, geraniums, fuchsias bu!ls, and similar plants are all effective on a formal terrace slope; or an alpine bank may lic constructed. In shady gardens a sloping terrace of hardy natire ferns and plants in tubs is attractive. See Awning; Brick; Crazy Paving; Italian Garden; Lawn: Rock Garden; Steps.

TERRA COTTA. This term. which neans balied earth, is applied to a class of pottery made of selected coloured clays, which

Terra Cotta. Fig. 2. Statue group designed for a fountain jet by Antonia Rossellino, 1427-1479
produce bufl', yellow, and red tints. The red is due to the presence of iron. The surface may be left unglazed, or covered with transparent and coloured glazes. The unglazed ware is porous, and includes butter coolers, lottles used for keeping water cool by evapor?. tion as well as pots for the purpose of admitting air to the roots of plants.
Because of its cleanliness and brightness it is in demand in the form of bricks and tiles for the paving of garden paths, verandalis, halls, and kitchens. Terra cotta jars, orna ments and vases of gool design are used effectively in the formal garden. The Doulton works are responsible for good development in modern glazed terra cotta tiles.
An idea of the beauty and antiquity of this clay fabric aud its durable quality is gained liy a survev of existing specimens in a muscum. The example of ancient terra cotta illustrated in Fig. 1 probably dates from some period during the 2nd millennium b.c. The primitive design of the painted and glazed decoration has no connexion with Persian art of subsequent eras, but is quite unimpaired. Exeava-
tions of beautiful terra cotta ligurines at T'anagra have thrown light on ancient Creek costumes.
Later, beautiful statue groups were executed in Italy by noted sculptors, and an cxample dating from 15 th century is here illustrated. luring the Renaissance the vitrified terra cotta enamelled in colours was introduced.
The older English potters employed terra cotta frecly for roof-ridges and finials, as well as for chimney-stacks, of which there are some fine Tudor exaniples. From the Low Countries came later that form of terra cotta with a tin-enainclled glaze which, under the name of Delft ware, gave the first impetus to modern decorated carthenware in direat Britain. Since then British potters have been so fully occupied in perfecting white-bodied ware of all descriptions that they have done little with portable terra cotta beyond making reproductions of Tanagra figurines and other ancient statucttes. With the exception of Della Robbia reproductions, large modern pieces of glazed and coloured terra cotta are for the most part unpleasing and crudc in design and colouring. See Delft: Faience: Majolica: Tiles.
TERRIER. Amongst the divisions into which dogs are grouped by the Kennel Club, the most numerous is the terrier family. Generally speaking, all thesc have characteristics in common, such as loyalty to their owners, an irrepressible vivacity, alertness, and fearlessness. Their keep costs little, and they take up no room indoors, being cqually at home within the house or outside. In the country they are ready for every sport.

As regards the various companionable qualities, there is little to choose betwcen them, but for protection or as a trusty guard cither an Airedale or bull terrier is to be recommended on account of its size, preferably the former. The bull terrier is somewhat headstrong un!css carefully trained, and he is scarcely so amenable to discipline as the other. The Kerry blue (q.v.), though lighter, is perhaps too ready for fighting to be a desirable companion for ordinary people. The red Irish terrier is also a reliable protector.

Fox terriers still stand foremost in popular csteem though the Sealyham has made great headway ; he is a dog for the country. The Welsh terrier, somewhat homely in looks, is an excellent companion, besides being cheap. Any of the Scottish varicties can be reconmended. The Cairn suits those who want a very small dog that is not a toy. Dandies are lovable little creatures with hearts of lions. See Aberdeen; Cairn; Dog; Fox Terrier ; Irish; Kennel ; Scalyham; Yorkshire, etc.

TERRINE. The original form of tureen is terrinc. A French dish is so called from terrine, which means an earthenware pan. This dish was composed of quails, chickens, pigeons and mutton, the neat being cut into portions and the whole baked in carthenware in the oven. Terrine is the name usually applied to the small earthen pot employed for potting foic gras and other savoury potted meats. See Tureen.

TERRY. Turkcy towelling is the kind of terry cloth that is most commonly used in the homc. Bath robes or dressing gowns can be nıade at home from this material, which can be bought in plain bright colours and also with coloured patterns. In making bath mats for Jloors a thick quality should be used, otherwise the mat will not easily remain Hat. 't'erry cloth is also useful for bathroom curtains and for nursery cushion covers.

TESTER: Of a Bedstead. The tester originally described the flat covering of material that was stretched on a frame above one of the bedsteads used in olden times. Soon it was used for the wooden canopy that was fitted on to many bedsteads, and for

'l'etratneca. Small pink blossoms of this evergreen indoor ahrub, which makes an attractive pot plant
this reason these are known as tester beds. Tester beds were popular in England during Tudor times. In many the tester is beautifully carved as are the bulbous turned posts that support it. In most of these bedsteads there are four posts, but in a few the head end is filled in with panclling as far as the underside of the tester: consequently two only are reguired, these being at the foot end. Sometimes a hiding place was made in the tester. See Bedstead; Tudor Style.

Tetanus. See Lockjnw.

TETANY. In the condition known as tetany spasmodic contractions of the muscles, mostly of the hands and fect, occur from time to time. In children it is associated with rickets, and in adults with disturbance of the digestion. It is treated by giving large doses of calcium chloride and by attention to the general health.

TETRATHECA. This is the name given 10 a greenhouse evergreell fowering shrub with red or pink flowers during the summer months. It thrives in the usual potting mixture in well drained pots in a sunny position in the greenhouse. Propagation is by cuttings. The necessary temperature a verages $50^{\circ}$, and plenty of water is necessary at all times.

TEUCRIUM. The small family of plants known as teucrium consists chiefly of hardy perennials with fragrant sage-like lcaves. They are suitable chiefly for the rock or wall garden and are increased by division. T. Chamaedrys has shining leaves and purplish, llowers in summer ; T. Marum is the cat thyme.

THALIA. This plant may be described as an aquatic perennial, of which only one kind, T. dealbata, is grown. It is a handsome purple-flowered plant for the margins of brooks and ponds where the position is warm and sheltered. It is hardy if roots are placed deep enough to avoid frost.

THALICTRUM. This is the name of a group of attractive hardy flowering plants with deeply cut, alnost fern-like leaves, and popularly called meadow rue. They flourish in ordinary well-drained soil and are increased by division in spring. Those most suitable for the flower border are aquilegifolium, 3 ft ., purple; flavum, 3 ft . yellow, and dipterocarpum, 4-5 ft., rosy lavender. Minus, which grows only 12 in . high. has yellow flowers; its variety, adiantifolium, is commonly called the maidenhair plant, because of the small, fern-like leaves.

## Thatching: The Process Explained

## Modern Applications of an Old and Attractive Method of Roofing

The reader of this article may with advantage consult the enrries that deal with the various types of building, eg. Bungalow; Cottage: House: Summer House. For other forms of Roofing see Roof; Slate; Tiles
Thatch has much to recommend it as a tools consist chicfly of the bill hook and a roof covering. It is warm in winter and cool somewhat similar but flatter knife, known as in summer, and when the thatch has settled an caves knife, about 18 in . long. This or a
down the ris- from fire is not serious in culuntry districts. It is not expensive as a roofing, but requires certain skill and ability to perform the thatching of a roof in a satisfactory manner. Thatch is suitable for roofing all manner of garden erections, and it is probably in this dircction that the amateur may use it.

Figs. 1 to 3 show the manner in which the present-day house is thatehed. The thateher's pair of stout shcep shears are used for trim. ming the eaves. One or two hand rakes with iron teeth arc necded, as well as ladders long enough to reach to the ridge of the roof of the building.

Other necessary articles are a supply of pegs, binding corl made of threc-strand hempen cord, sometimes known as marling, a wooden mallet, and some stout cord with a running

Thatching. Picturesque example of a modern thatched roof on a little country inn
noose to carry the thatching materials from the ground to the roof.

Preparing the Straw. Thatching customs vary in most counties. In Norfolk the spear grass found in the fens is largely employed and is the strongest and best thatching material. In Sonicrset and Dorset straw is extensively used, and so on with other districts. To begin with the material is made into bundles known as boltings or covings when the material is straw, as threeves when prepares from heather, and as fathoms when of reeds. Thesc arc delivered to the site, when the roof has been prepared for them, and are unloaded and stacked.
The preparation of the straw is important Straw of a dry, loose character cannot bc packed as tightly and securely as damp straw ; for this reason the straw should be well douched with water and turned over with a fork until it becomes thoroughly moistened The hear must then be slightly compressed

Thatching. Fig. 1. Rooi prepared by nailing wooden runners to the joists. Fig. 2. Thatching begun by sewing the straw with twine to the runners Fig. 3. Laying a plaited ridge roll, one way of finghing off the apex of the roof Courtesil of Boulton \& Paut, Ltd.
by beating with the fork or by treading. The
straw should next be drawn from the bottom of the heap where the pressure is greatest. The usual method is to grasp as much straw as can be gripped by both hands held close together. The straw is then drawn out by a quick movement of the arms towards the right, followed by a swing over to the left, finally laying the bunch of straw at the worker's feet with the thicker end to his right hand. This work of yealming, as it is called, is usually undertaken by the thatcher's assistant.
When a sufficient quantity of this partially straight straw has been collected the worker goes through it, using his fingers to regulate it and to remove any loose portions, at the same time drawing the bundle to his fect until the layer amounts to as much as he can hold in the grip of both liands. Great care should be exercised to exclude all short ends and picces of straw, so that, when properly prepared, the ycalm will he perfectly straight

The yealm of straw must then he gathered in the hands and a small quantity pulled out at one end, turned down and wound round the top of the yealm, forming what is known as a staple. The projection thus formed at the head of this staple prevents it from locing withdrawn after it has once been inserted in the turves as described below. A yealm thus formed should never be broken, but kept firm and secure until it is placed in position. As the yealms are completed, they are placed crossuise on a short rope or cord, the thick and the thin ends alternating. When sufficient in number and weight for a man to carry, the rope, which should have a running noose. is drawn round the yealms, which are in this way pulled on to the roof.

Two Methods of Thatching. There are two ways of using straw. One is to lay a covering
of fibrous turf over the roof and to push the straw through the turves, while the other is to sew the straw directly to the roof. To prepare the roof for thatching by the first. method, the rafters must be fixed on to the roof in the usual manner, wooden battens being nailed on at about 6 in. apart. These battens should be about 3 in . broad. The turves arc placed upon the roof, working from the bottom and proceeding in an upward direction as with slates. When cutting the turves a thick curved cutting-iron must be used, so as to obtain turves thick in the centre but gradually tapering off towards the sides. Then, when laid on the roof, the overlapping

alternative, two pieces of wood may be utilized, the boards being cut to the same length as the roof and fixed so as to overlap the thatch for some distance on each side. This method of thatching is, perhaps, more extensively practised than the one above described, as it is often impossible to obtain

firm, fibrous turf. Thatch should overhang the walls to a considerable extent, to allow the drippings to fall clear. Dormer windows, valleys, and hips are all covered in the gencral run of the work. Separate cdges will make the turf covering level and the roof will be of one thickness throughout.

For laying the staples of straw a thatching iron will be necessary. This implement is slightly forked at the apex in order to catch the twisted head of the staple. In this manner the latter is pushed through the turf, and is prevented from coming out again by the head of wound straw. The work of laying the staples must be commenced at the caves, and should proceed upward until the ridge is reached ; at this point a layer of turves is placed over the straw in order to form a bolster, or well-delined ridge, and the thatch. ing is then complete. An alternative method of finishing off the ridge is to fix in place a tightly plaited straw roll, as shown in lig. 3.

When preparing the roof for the sccond method of thatching, namcly, sewing the straw directly to the roof, the rafters are laid, the wooden battens nailed on, and the straw prepared in the same way. The straw is then sewn directly to the battens, commencing at the bottom and working upward to the ridge. Sewing twine is usid for this purpose, and the work will be found quite a simple operation after a little practice has been obtained. In order to finish off the ridge turves may be requisitioned, as in the former method. As an
gutters are unnecessary, and the cost of a broken roof is thus less than when covered with tiles, which have to be carefully fitted.

Heather and Reeds. In ccrtain districts heather is used extensively in the thatching of dwelling houscs, and particularly rustic summer houses and sinilar buildings. This material is not always procurable in abundant quantities, but in the north and central counties of Scotland it forms the staple medium for thatching purposes. When carcfully cut, heather will require but little preparation beyond straightening out. The roof is prepared as in the case of straw thatching by the second method, and the heather sewn fairly tightly and closely together. This makes an excellent and very durable roof.

Rceds, where they are procurable, are also a valuable material for thatching purposes. They arc used in a similar manner to straw, being either sewn direct to the roof or inserted through turves. Broom is used in other districts in a similar manner to heather

On the roof of a dwelling-house, ten bundles, or 5 cwt., of straw will be required to each square of thatch. A square is 100 sq . ft. When thatching is carried out in a thoroughly expert and experienced manner, the roof should remain quite watertight for about 30 years, if composed of the finest quality wheat straw, or for 40 years if rueds are employed. If the work is done indifferently it may not last for more than 10 years. Much of this information is taken from Leaflet No. 236, issued by the Ministry of Agriculture.

Fig. 4. Thatched roof nearing completion. Note the ornamental finish of the ridge around the chimney stack, and how the thatch overbangs the gable ends of the roof Courlesy of Boulton \& Paul. Ltd.

## Theatricals for Amateur Actors

## Some Practical Hints on Play Producing for Amusement

This article contains useful information for those desirous of giving entertainments of this kind in a simple manner. See also Fancy Dress; Makc-Up; Stage

When a theatrical performance has been decided on the most important step is to sccure a good etage-manager or producer. A professional is cometimes engaged to produce the play and has the assistance of an amateur stage-manager. For the less ambitious type of performanco the amatcur stage-manager combines with his other duties those of producer. Some experience, ability to play cvery part in the piece, tact, inperturbable temper, rcadiness to listen to arguments, and lack of obstinacy are qualities required in the producer-stage-manager
The next point is the choice of a play. Consider the aren at disposal ; twelve people cannot be expected to move and act naturally in a space which can only accommodate three. Consider the height; the balcony scene in "Romeo and Juliet" cannot be given with only seven feet of headroom.
Consider the inevitable limitations of the scenery. Consider the capabilities of the actors as a combination. A simple piece well acted all round is more satisfactory than one star performance badly supported. Consider, above all, the audience; in ninety-nine cases out of a hundred they prefer to be amused. Finally, it is a mistake to select a piece which many of them have probably recently seen performed by a first-rate prolessional company.
The casting of the piece naturally follows, and there are advantages in leaving this task to the stage-manager or producer. Do not in any case choose hurriedly, for mistakes cannot afterwards be rectificd easily.
The producer must study every part in the play. He should work out the inovements and positions of every character from rise to fall of curtain. When all this is accomplished, a convenient date is fixed for the first rehearsa!. At this the producer should read the play through, afterwards giving each performer some idea of the character he is playing, and generally clearing away any difficulties. The second rehearsal should take place on the stage, or on a space of the same size, with the furniture arranged as on the night, and the positions should be gone through, giving time to the actors to mark them in their books.

## Importance of Rehearsals

The next three rehearsals, assuming the play to be in three acts, should be devoted to one act apiece in turn. The sixth, seventh and eighth will be well employed in the same way, but now rigidly enforcing the rule " no books," supplying all the properties required, and insisting on the actors playing as if it were the actual performance ; paying special attention to the principal characters, and letting no awkward positions, meaningless or cxaggerated gestures, or wrong intonations or emphases pass uncorrected. Two or three rehearsals of the whole play, not counting the dress rehearsal, should then be sufficient.
The dress rehearsal inust be carried out as a performance, and the stage-manager will have to see the stage set and all the stage properties in place; perhaps make up the actors: get the beginners on the stage ; draw the curtains; prompt-though it is wiser to appoint a special prompter; see that each actor is at the proper entrance in time, and has any hand propertics needed ; close the curtains at the end of the act; change the furniture, if necessary; start the music, if any ; and so on until the curtain falls.

A platform raised two feet from the floor of the room adds to the enjoyment, but is not absolutely necessary, and unless the room is 14 feet high should not be attempted. The
drawbacks against using the floor of the room for the stage may be mitigated by setting the front row of seats as far back as is consistent with the rumber of spectators; by using low seats for the front rows; and by reducing as far as possible the number of scenes in which the actors themselves are sentcd.

The proscenium is the partition which divides the audience from the stage, carries the curtain, and forms a frame for the scene. One of those rooms partly divided into two by an archway gives a proscenium ready made. Failing this, a built-up proscenium is not altogether essential, as an entertainment can be contrived by selecting scenes from the works of the older playwrights, all of which were so constructed that the dramatis personae simply walked on at the beginning and off at the cnd, or by picking out more modern plays which do not commence with the discovery of some of the characters or end with an una voidable picture. A couple of screens high enough to conceal completely those on the stage and wide enough to meet in the middle when drawn out from either side will serve as a combined proscenium, curtains, and wings for those waiting their entrances "off," and entail a minimum of trouble and expense. Such screens can be constructed to the desired size, of light wood, by a professional or amateur carpenter, and covered at home with cheap material.

Practical Curtains. A more ambitious arrangement is attained by the use of curtains. Iron piping, about an inch in diameter, makes the best rod for these. One piece, the full width of the room, and an upright at each end against the wall sccurely fastened to the first, will be sufficient if the room is not wide; but it is safer to provide a second upright on each side at the front corners of the stage. The distance of these from the walls must depend upon the space available, but not less than three feet on each side is desirable.

A tie rod, close to each wall, firmly attached at the point of junction of the crossbar and support, sloping back at an angle of $45^{\circ}$, and screwed through an eyehole to the lloor, combined with the supports for the scenery, should provide the necessary rigidity. If these are insufficient, similar ties may be attached to the tops of the inner supports running up stage parallel to the walls. Sufficient rings for the curtains should be placed on the crosspiece before the uprights are attached to it.

The side curtains should be wide enough to fell into folds, with small bags of shot or little leaden weights sewn into the bottom hem to prevent flapping. Bolton sheeting is a good
selection for material. A valance across the top adds to the appearance but is not essential. The best effect is produced when the proscenium is carried right up to the cciling, but the essential height is about 8 ft . The ends of all rods touching the walls should be wrapped in some soft material to prevent damage to paper or paint.
The front crosspiece will carry the curtains. These should meet in the centre, drawing back to the sides like ordinary window curtains, and by a simple arrangement of the cords may be closed and opened by one person. They should be worked from that side of the room in which the door is situated. The best cord lor the purpose is ordinary picture-cord. Care should be taken to see that it is in good condition, for the breaking of the cord at a critical moment is a humiliating accident.

## Hints to Ensure Smooth Running

A few weights at the corners of the curtains, and at intervals along the bottom, may be added to keep thein steady, and a little blacklead rubbed along the top of the rod will facilitate smooth running, while a hook just inside onc curtain, about three feet from the floor, to fasten into a ring attached, at the same height, a lout four inches inside the other is serviceable in preventing accidental openings Do not forget to unfasten the hook before starting to open the curtains;

Scenery in any way approaching that used on the professional stage should not he attempted. In the cramped space at disposal even one change will be difficult and more than one almost inpossible, so that the choice of a play would he restricted to a one-act play, or to longer pieces, the action of which is all laid in the same scene, and in that case the walls of the room itself will be more convincing. Where more than onc scene is demanded, curtains of the same colour and material as those for the front of the stage are better than indifferent scenery and long waits between acts.

A rod identical with that supporting the proscenium should be fixed at the back, but the interior uprights may be placed a foot or eighteen inches nearer together than those in front, and in an ordinary room the two against the walls may be safely dispensed with. The back rod should run two or even, if space allows, three feet away from the walls of the room to permit of free passage behind. The rods for the side curtains should start from the end wall, be secured to the back uprights, and to the front horizontal rod one foot from the edge of the proscenium away from the centre. The curtain on each side should not extend to the front, but should leave an opening of about two feet to serve as an entrance to the stage. If the back curtain is divided down the middle the two sides may be drawn back when necessary to provide a centre entrance.

The furniture will show that an interior is meant ; a standard lamp, lighted, will indicato

Theatricals. Easy method of arranging stage and curtains
night-time : and iugenuity will doubtless used in Great Britain. On the Fahrenheit suggest conventions to indicate an exterior scene. The programme, moreover, will tell the audience what each scenc is supposed to be, and if the play is well acted they will never feel the absence of scencry.

A row of footlights is not practicable where space is linited, and is apt to cause hard, unbecoming shadows when not properly balanced with other lighting. If a chandelier hangs in the middle of the room, a sheet of tin or even white cardboard of sufficient depth to cut off the light from those seated farther hack will not interfere with their view, and will, at the same time, serve to reflect the light on to the performers.

Should there be no central light, or any way of improvising one, side lights alone nust suffice; in that case, given electricity, wooden battens should carry cight or even ten bulbs apiece.
If lamps are the only resource, each should be placed in a two-sided screen reflector large enough to enclose it completely, painted white within and placed on a steady support outside, but close to the proscenium, the outer side of each screen being parallel with the front of the stage. A few trials on the spot will soon show the best position for these to ensure the maximum of light on the performers, without impeding the view of any member of the audience, bearing in mind the fact that a broad diffusion, not a concentrated glare, is nerded.
The first thing for the performer is to learn the author's words and the cues-that is, the ends of speeches which precede his own; the second, to read the play through with care to find out what his character is, how to make up, dress, etc., and so form a concrete image of the personality of the part. Tricks and mannerisms which would be appropriate should be tried; those minor movements which come under the heading of "by-play" or "business" and where and when each is to be employed should be settled, and always when going through the part kept to its appointed place. Each speech in turn must be gone through and the meaning duly emphasised in order to convey this to the audience. Rehcarsals should not be wasted in learning parts, but in fitting the figures conceived into the rest of the picture, and developing the general effect, for play-acting is teamwork in which the harmonious interaction of all the per formers is essential.

THERM : In Gas. The therm is a unit of measurement introduced by the Gas Regulation Act of 1920. A therm is equal to 100,000 British thermal units or B.Th.U., and is the hasic unit upon which charges for the supply of gas are made to the consumer by the public gas undertakings. See Gas.

## Thermionic Valve. See

 Valve; Wircless.THERMOMETER This instrument is used for measuring heat. One is usually part of a weather glass, this being used to measure the heat of the atmospherc. The heat of the body is measured by a clinical thermometer.
Heat on the thermometer is measured by ilegrees. There are two scales in ordinary use, Fahrenheit and centigrade ; there is also a third method, namely Réaumur, which is not much

Thermometer for the greenhouse Courles" of Negrelli i Zambra
$212^{\circ}$. On the centigrade, which is the one most used in scientific circles, freczing point is $0^{\circ}$ and boiling point Read scale, freezing point is $0^{\circ}$ between and boiling point is $80^{\circ}$

Lines

It is quit vert realing casy to con into thang on one scale another. For instance, $55^{\circ} \mathrm{C}$ is equal to $131^{\circ} \mathrm{F}$. This is done by the following formula :

## $55 \times 180$

100
The formula for the reverse process, i.e. converting Fahrenheit into centigrade, is :
$\frac{(131-32) \times 100}{180}=\frac{99 \times 100}{180}=55$ Clinical Thermometer. A selfregistcring instrument known as a
clinical thermoncter is used in medicine clinical thermometer is used in medicine for measuring the temperature of the
body. The tube in which the mercury rises is very much constricterl just above the mercury bulb, so that when the mercury rises to a certain height in taking a temperature it remains at that height until shaken down. This is what is implied in the term self-registcring.

In Great Britain clinical thermometers arc graduated according to the Fahrenheit scale, but on the Con-

Clinical Thermometer, and diagram it correctly it correctiy
 tinent the centigrade scale is adopted. On the former scale the thermometcr registers between $95^{\circ}$ and $110^{\circ}$, and each degree is subdivided into 5 parte, indicated by shorter lines than those denoting degrecs. In reading off a temperature the subclivisions are read as decimal fractions; thus one subdivision is $\cdot 2$, two 4 , and so on. The normal temperature of the body, $984^{\circ}$, is shown by an arrow running across the scale.

Before proceeding to take a temperature the nercury should be brought down $1^{\circ}$ or $2^{\circ}$ below normal, and this is accomplished by grasping the stem firmly with the thumb and index finger and making several forcible flicking movements with the thermometcr. There is also a device, here illustrated, for lowering the mercury in the tube by making the case $B$, containing the instrument, revolve rapidly on the swivelled crosspiece A.

The method of taking the temperature is described under the heading Temperature (q.v.). If therc is occasion to use the instrument several times during the day it will be convenient to keep it in some antiseptic lotion in a glass, a picce of cotton wool being placed at the bottom of the glass to minimize the risk of breakage. See Prescrving.

THERMOPSIS. These are hardy herbaccous perennials with pea-like flowers in early summer. Montana, $2 \mathrm{ft} ., \mathrm{ycllow}$, and barbata, 12 in., purplish, are the hest kinds. They thrive in ordinary well tilled soil and dislike being disturbed. The best method of propagation for these plants is by seeds.

THERMOS FLASK. This is the name of a kind of vacuum flask for retaining liquids in a hot or cold state. The glass vessel can be replaced at a moderate cost if it gets broken, but with ordinary care this should seldom be necessary. The tlask should be left uncorked when not in use, as otherwise the stopper may become musty. See Vacuum Flask

THERMO-SYPHON: Cooling. In the great majority of cases the internal combustion engines used on motor cars are water cooled. The thermo-syphon method makes use of the natural law that a given volume of hot water weighs less than an equal volume of cold water. The water, as it bccomes heated in the cylinder jackets, expands and rises, giving place to cooler water entering from below, after passing through the radiator. By suitably arranging the position of the radiator in relation to the engine, the purely automatic circulation of the water through the medium of the radiator keeps the enginc at a definite temperature within limits.

Apart from radiator position, there are threc points to be considered, namely the capacity of tho radiator, the amount of cooling surface, and the diameter of the flow and return pipes. These should be as large as possible, not less than $1 \frac{1}{2} \mathrm{in}$. in diameter, so as to restrict the passage of the water as little as possible. A fan is usually filted to force air through the interstices of the radiator, so that the cooling action is to this extent independent of road speed or wind.

The tempcrature for a watercooled eugine should lse about $200^{\circ} \mathrm{F}$. The water should remain somewhere about this figure during the whole time the engine is running. To obtain this result the difference of height between the bottom of the cylinder jacket and the bottom of the radiator is determined by experiment, so that the water, after passing through the radiator, will still be at a fairly high temperature when it again enters tho cylinder jackets.
The higher the bottom of the cylinder jacket in relation to the bottom of the radiator, the slower will be the thermo-syphon action. If the bottom of the radiator is level with that of the cylinder jacket, the fullest advantage is taken of the system, and therefore the water, as it enters the jackets, will be at a very low temperature. The most effective arrangement is shown at $\mathbf{A}$ in the illustration.

If the relative positions are as slown at $B$, the amount of cooling surface is considerab!y reduced, and the water will still be at a fairly high temperature on entcring the cylinder jackets.

When the front of the velicle is lifted, as in climbing a stecp hill, a varying extra amount of cooling surface is automatically provided, because for the time being the difference of level is increased. This is all to the good, hecause it comes at a time when in all probability the engine of the vehicle will be working at full output on the low gear. With the radiator placed behind the engine tho reverse is the case, which probably accounts for the lact that for this system pump circulation is invariably employed.

Temperature Control. By the incorporation of a thermostat in the thermo-syphon syetem
the temperature of the cooling water can be of fracture of the thigh: It may affect the automatically regulated. The thermostat, upper extremity, especially the neck, the shaft which is pre-set to the desired degree, opens or the lower extremity. Fractures of the or shuts a valve which governs the flow of circulating water. An increase in flow brings about an increased cooling effect, and vice versa. Thus the temperature remains approximately uniform, irrespective of vehicle specd or weather conditions. See Motor Car ; Pump: Radiator.
THICKENING: In Cookery. A mixturc of which flour is the principal ingredient is used to thicken soups and gravies, to convert stock into sauces and for binding cutlets and rissoles. It is used also to thicken milk for invalids, 1 oz. flour being used to every pint of milk. The llour is first mixed smoothly with a little cold milk and the whole then boiled for ten minutes.

The most important thickening is roux, both brown and which become painful by fing of equar proportions of the the phile one too large will be finest white flour and butter cooked together continual!y dropping off. until the two are amalgamated.

Roux is fried or baked if brown roux is de. sired. It is simply stirred over the fire until the flour is incorporated with the fat for white roux. Occasionally a thickening of butter and flour which has not been previously cooked is added to the liquid. It should then bc worked together on a plate with a knife.

A more simple method is to mix the llour into a thin paste with cold liquid and stir it into the gravy or sauce to be thickencd. This method, however, has a tendency to impoverish the sauce, while the addition of butter softens and enriches it. Colouring must be added if a brown sauce is required.
Certain grains, such as crushed tapioca, rice, semolina or sago, eau be used as thickening. The grain should be sprinkled into the liquid while boiling and lakes from 10 to 15 min. to cook. Pearl barley is used to thicken broths, but must be blanched first, and given a much longer period to cook. Arrowroot and cornllour are frequently employed in thickening, first mixed with a little cold liquid, and they must be stirred in gradually.

Eggs may be used to thicken white sauces, soups and milk, also for custards and light puddings. The eggs must always be thoroughly heaten before being mixed with the liquid, and must never be allowed to reach boiling point, or they will curdle. Egg. worked with sugar make a thick basis for many kinds of cake, and when mixed with oil or butter form the groundwork of salad dressing.

Lentils and peas when cooked and made into a puree thicken vegetable soups. Haricot beans may also be used for this purpose. Oatmeal is occasionally employed as a thickening for soups, but it cannot be strained away, neither does it become absorbed. See Browning; Flour ; Gravy ; Sauce ; Soup.

THIGH. The thigh bone or femur in man belongs to the class known as long bones, that is to say, it consists of a shaft and two expanded extremities. The head is received in a cup-shaped cavity on the haunch bone, known as the acetabulum, so that a ball and socket joint is formed. The average length of the bone in an adult male is about 18 in . the lower end of the femur articulates at the knec with the tibia. These are possible dangers

THINNING: In the Garden. When applied to trees and shrubs thinning out means the removal of old and superlluous branches. The term is also applicd in gardening to the removal of unwanted seedlings so that those remaining shall have proper room for development. Fruits too must be thinned to allow those left to reach full size. In thinning grapes care should be taken first to cut out all small berries and then those in the eentre of the bunch. It should be noted that unless grapes are correctly

Thinning Fruit. Shated portions show how to evsure fine specimens Bu special arrangement with Amatrur Gardentng

THISTLE. The most ormamental thistle being essential that the machine shall he for the garden is the cotton thistle or onopor- capable of driving the engine so that full don, tall handsome plants, 6 ft . or more high advantage can be taken of the engine as a with pale purplish tlower heads. The chief retarding force when descending steep hills, kind is Onopordon acanthium, commonly or when wishing to slow down the machine called the Scotch thistle. These thistles are gradually without recourse to the brakes. most suitable for the wild garden: they With all types of huh gear designed for motor flourish in ordinary soil and are raised from cycle use some form of clutch is incorporated seeds sewn out of doors in spring.
THORN APPLE. This group of annuals and greenhouse shrubs belongs to the potato family. The botanical name is datura (q.v.).

The common thorn apple (Datura stramoniums bearing large prickly fruits sometimes appears as a weed in gardens.

THORNBACK. Being a species of skate, the thornback is a salt-water fish found round the British coasts. It can be cooked in the samc way as skate. See Ray ; Skate.

THREAD. It is an cconomy not only to buy the best quality of thread but to secure the right kind for the purpose in hand.

Domestic sewing cotton consists of six separate strands twisted together to the requisite tightness. No. 24 is a strong coarse thread for buttons, 40 or 50 for hand searcing. For sewing machines thread of 60 or 80 is suitable.

Linen thread is stronger but more uneven than cotton and especially useful for bootbuttons, carpet-sewing. rug-backing, and similar uses. Silk sewing thread is userl throughout by the best tailors; for buttonholes which have to take much wear silk buttonhole twist is indispensable. Merccrized cotton can be used for buttonholing but does not give the same satisfaction.

Threads are specially made for crochet, embroidery, knitting, and other forins of fancy work, and experience has taught the manufacturers which numbers are best for particular purposes, and their advice is always valuable, as threads are prepared with a view to the needles or hooks with which they are to be employed, and with an eye to appearance. Artiticial silk threads are largely used for embroidery as well as for knitting, and they may give trouble unless suitable needles are used. See Crochet; Embroidery ; Knitting ; Sewing Machine.

THREE-SPEED GEAR: For Cycles. Variable speed hub gearing is used on pedal cycles and motor cycles. The latter is dealt with in the article on (iear. In motor cycle practice this system has largely bcen displaced by one employing spur gears, located between the engine and rear whecl.
The chicf difference between the two types of hub gear !ies with the method by which the gears are operated; with the pedal cycle gear the mode of operation is through the medium of ratchet tecth and pawls, but with the motor cycle type of gear the niethod of operation is by means of clutehes that, apart from bringing the repuired gear into operation, also lock the required gear as solid with the huls: i.e. there is not a i.e. there is not a
frec-wheel action, it s a means by which the engine may be disconnected from the hub.

Fig. 1 shows in part section a three-specd coaster hub for pedal cyeles. Although termed
a three-speed gear, actually only two geared also in engagement with the stationary pinion speeds are employed, namely, a low speed and A rotating the cage $B$, of which the ratchet a geared-up speed. The middle speed is teeth $K$ are a part, and these teeth engage called normal, meaning dircet drive, i.c. the the cage pawls $H$, that are a part of chain ring drives direct to the hub shell by the hul) shell D, thereby means of ratchet teeth and pawls. Fig. 1 is a completing the drive. This detailed drawing in part section of the com-being the low gear, C, M, plete hub. The outer shell that carries the and $N$ will be rotating at whenl and tire is driven on all three specds by a greater speed than the ratchet tecth and pawls, so that it is possible to const or frec-wheel with any of the speads.

Fig. 2 is a diagrammatic lay-out of the gears. A is the stationary pinion, $B$ is the Hoating cage that carries the four planet wheels, and C is the outer internally toothed ring with which the planets are always in engagement ; the pinion $A$ is also in constant mesh. with the planets. To obtain the low gear the outer ring $C$ becomes the driven member, driving the eage $B$ through the mediun of the four planet wheels that are attached to the cage by their bearing pins. Thesc planet wheels are also in engagement with the stationary pinion $A$, so that as they are rotating the plancts will travel in the same direction as the outer ring, but will move more slowly. The final drive is from the cage B to the hub shell D.
The high or geared-up gear is obtained by a reversal of the foregoing, Fig. 3. The cage $B$ is the driven menber, which by rotating causes tho four planet wheels, through the medium of the stationary pinion A, to revolve, and these by so doing rotate the outer ring $C$, but at a greater speed than that of the cage $B$. In this case the final drive is from the outer ring C to the hub shell D , it being understood that the power applied to the driven member in both cases is through the chain ring shown at M, Fig. 1 .
Fig. 4 shows the operation of the low gear. The direction of the drive is transmitted from M to N , then via the ratchet teeth T . They engage with the pawle $Q$, which are a part of the outer ring $C$. Then the drive is through the medium of the planets $E$, that are

Three-speed Gear. Fig. 8. Derailleur gear, in which a free-wheel with two or more sprockets are used, chain being actuated by a lever-and-cahle control Courtes!y of Cyclo Gear Service

Derailleur Gears. There is another type of variable speed gear-considerably used on the Continent-in which a free whee! with two or more sprockets is emploved. the chain being moved from one sprocket to another by a lever-and-cable control on the top tube of the bicycle frame. A tension cog takes up any slackness of the chain between the smallest and largest sprocket. When the control lever is moved a rotary morement is given to a quick thread on which the actuating sprocket is mounted, so that the sprocket moves laterally into line with the cog sclected. The deraillcur gear, as this type of change-gear mechanism is known, is obtainable as a two, threc, four, or sixspeed gear, and the twospeed pattern (illustrated and pawl $T$ and $Q$, thence
via the Paw ! and ratchet $F$ and $G$ to the hub in Fig. 8) can be fitted to an existing whecl shell D. The drive is now solid, the gear wheels without alteration other than lengthening running idle owing to the stationary pinion $A$. the chain.

Fig. 6 is the high or gcared-up speed. THREE-WHEELED CAR. The "threeThrough the medium of $S$ and the thrust wheel "car is a step between the motor cycle collar $L$ the cage 13 with the outer ring $C$ is with sidecar combination and the four-wheeled drawn further still to the right. By so cloing ear. An advantage is that in the cyes of the the ratchet and pawls T and Q, Fig. 5, are law it is a motor cycle and trailer, and theredisengaged, and the ratchets $P$ and $W$ tale fore comes under regulations of licensing up the drive. The eage 13, of which the ratehet different from those which apply to a car. teeth $P$ are a part, is the driven member. The tax on a three-wheeler is $£ 4$ per annum, through the medium of the planets E , which whereas a four-wheeler of the same horsein turn drive the outer ring C. The pawl and power would be taxed $£ 9$ or $£ 10$. Moreover ratchet F and G take up the drive to the hub the design is simple, and since the back axle shell D. Diagrams 4,5 and 6 should be read with its complicated worm, or bevel and in conjunction with Fig. 1. The arrangement crown whecl, and differential is eliminated, the of the controls is shown in Fig. 7 below. cost of construction is distinctly low. The

weight of the completed vehicle is somewhat less than that of a similar four-wheeled type.

This lightness of weight gives the vehicle a relatively high performance, equalled only by high-powered cars at much greater cost; and it becomes a very fast and relatively powerful car at the price of a motor cycle and sidecar. This is by no means the limit of the appcal of the three-wheeler, for therc are on the market soveral excellent "family models" which give the same accommodation as a small four-seater car with much lower first cost, running

Three-wheeled Car. Morgan three-wheeler, lamily moded Courtesy of The Motor Cucle
suitable for the Hower horder or rock garden. The commonest is Armeria vulgaris (or maritima), a favourite cdging plant which bears light rosecoloured flowers in summer: laucheans is a varicty with blooms of decper colouring. Sea pink is another name for this plant which grows wild among the rocks by the sea side in the West ol England. Two goorl and maintenance costs. Most three-wheelers laller thrifts suitable for the border are lati are driven by a two-cylinder engine of the motor folia and plantaginea, 12 in ., with rose-coloured cycle type which drives the back wheel by blooms; of the improved varietics raised ir means of chains; in one design the power is applied direct to the front wheels, thus obviating the use of long chains.

In the Morgan car the power unit is a twocylinder engino either of the air-cooled or water-cooled type which transmits power to the back wheel hy means of a short shaft and chains. There is no gear-box in the accepted sense of the term. From the shaft the drive may be taken at will through either of two chains, which provide different speed ratios. The type of borly on this chassis varies from two-seater tourers and four-seater "all. weather models" to twoscater "super sports" models capable of over a hundred miles an hour.

The B.S.A. three wheeler is driven by a twocylinder air-cooled engine, but, unlike the Morgan. the drive is on the front wheels and not on the single rear wheel. This form of construction is moderately cheap, since all the mechanical elements are concentrated at one end of the vehicle.

Various other types of three-wheel vehicles have becn introduced from time to time but have not caught the public fancy, and are no longer made, except the Seal, which is in effect a sidecar combination built as one machine instead of two. It is fitted with a two-seater body on car lines.

Theoretically the three-wheeler is not so stable as a four-wheeled car, the relative stability of the two types of vehicle approximating to that of a three-legged stool and the conventional chair, respectively. In practice, however, the disadvantage of a threcfold support is not so apparent, and in the hands of an efficient driver the three-wheeler may be reckoncd as safe as the four-wheeled car, though it requires greater skill in driving Motor cyclista prohably make the best drivers, since many motor-cycling conditions obtain.

Manufacturers as a rule do not equip a three-whecler with a reverse gear, and the steering gear is not of the somewhat complicated type used on a car, with the result that steering is perhaps a little more fatiguing. Advantages of the three-whecler include lower weight, greater power in proportion to weight, greater economy in petrol, simplicity of construction, and lower taxation.

A three-wheeler ranks os a motor cycle, therefore the age limit for holding a licence to drive it is sixtcen years, instead of seven teen, as in the casc of a car.
THRIFT. This is the name of a low growing evergreen tufted plant (armeria)

emulsion, and there are various proprietary insecticides. See Insecticide; Peas; Spraying; Syringe.

THROAT. The space behind the mouth, including the fauces, pharynx and larynx, is called the throat, though the name may also be applied to the front part of the neck. A sorc throat, which usually means some degree of inHammatory disturbance, may have many causes. It occurs most frequently, perhaps, in connexion with a common cold, but it may happen also at the beginning or in the course of other infections diseases. It may also be due to tobacco or some other irritant.
In young children the throat may be sore and there may be little to indicate the fact. For this reason the carly stages of diphtheria may be overlooked. It should always be the rule, therefore, to examine the throat of a young child when it is ailing. To do this the child should be held where a good light will shine into the mouth, and the tongue should be depressed with the llat handle of a teaspoon.

A number of methods are available for the application of remedics to a sore throat. Gargling has the disadvantage that the movements made in carrying it out themsclves tend further to irritate very sensitive parts. Patients who are old enough to do so may get more good from simply allowing the gargle to lie in contact with the back of the throat for a
minute or two. In acute conditions spraying is better, or the parts may be steamed.
Benefit may be derived from the application of hot or cold compresses to the front of the neck. These are of several thicknesses of flannel or lint, covered with gutta-percha tissue or oiled silk. and a bandage. Chronic sore

Thritt. Rosy flower heads of the nopular sea pink
throat may follow the acute or may result from over use of the voice, dyspepsia and other causes. See Adenoids; Cough; Croup; Crowing; Diphtheria; Eustachian Tube; Gargle; Inhalation ; Laryngitis ; Larynx ; Quinsy ; Tonsillitis.

THROATING. This name is often given to a groove cut on the underside of a projecting portion of a building to check the passage of rainwater. When rain falls upon the top surface of the sill it spreads out and llows over the edges; by capillary attraction it flows underneath the sill, and in the absence of a throating groove it continues until it meets the surface of the wall, where it runs partly down the surface. If a groove is cut near the front cdge of the under side of the sill, the water gathers there, and by its weight drips from the cdge of the gronve, thereby kceping the remainder of the sill and the wall dry.
Throatings are not always sct in a hori zontal position. Examples are found in many windows in a vertical position, both on the moving part and on the framework or fixed part. The purpose in both cases is to act as anti-capillary grooves, which, by collecting the rainwater, provide a channel for it to run down and drain away.

THROATWORT. This handsome green house plant, 2 ft . or so high, bears bunches of light blue flowers in summer: its botanical

name is. Trachelium caeruleum. It is easily grown in a compost of loam, leaf-mould and sand and is increased by cuttings in late summer or by seeds sown in June. During vinter a temperature of 50 degrees is high enough. It is sometimes planted in flower beds for the summer months.
THROMBBOSIS. The formation of a clot of blood in the heart or in a blood vessel, usually a vein, is called thrombosis. If thrombosis succeeds in obstructing the flow in a blood vessel, little may happen if the blood is able to move on through other blood vessels, but when it occurs in one of the principal veins of a limb it causes dropsical swelling of the limb, with stiffness and tenderness. The symptoms and consequences of thrombosis depend upon its site. See Embolism; Varicose Vein.

THROTTLE : In Car and Cycle. With all makes of carburetter the device known as a throttle is used to control the anount of gas entering the cylinder on the induction stroke. There are two types in common use, namely, the butterfly and the piston, the former being the more popular for motor car work and the latter for motor cycles.
The butterfly type is mounted on a small shaft positioned across the centre of the mixing chamber and over the jet. The closed position is capable of fine adjustment for control of the amount of mixture past the pilot jet, used for keeping the engine running very slowly while the vehicle is stationary. The piston type operates by rotary or sliding movement. The amount of throttle opening is graduated, apart from piston movement, by a $V$-shaped slot cut in the side of the piston, and with the multi-jet carburetters the slot is so shaped that as the throttle opening increases the jets are uncovered in turn.

A proper use of the throttle consists of something more than opening and closing it, according to the engine power required. It is imperative that the speed of the air sucked past the jet should increase as the throttle is opened if a uniform mixture is to be retained. In other words, unless the speed of the engine rises with the throttle opening, the suction on the jet will fall, with the result that the mixture will be relatively weak. Therefore, although the throttle is wide open, the engine will not be giving its full capacity of power.

When the vehicle is climbing a hill and the revolutions of the engine fall off to an appreciable extent, to open the throttle wide will only result in making matters worse. The correct procedure is to change to a lower gear, speed up the engine, and, if the nature of the gradient is suitable, change up again as quickly as possible, at the same time gradually opening the throttle as the speed of the engine increases.

Wear of the bearings of the buttertly throttle, and wear between the piston and cylinder of the piston type, is of considerable importance. Especially is this the case when the engine is running on the pilot jet, because, owing to the throttle being practically closed, air will be drawn in at any possible point, thereby seriously upsetting the mixture. The only cure is to renew the worn parts in the case of the piston throttle, and rebush the bearings of the butterfly pattern.

The speed and power of the internal combustion engine are directly allied to throttle control. Therefore, careful periodical attention should be given to all working parts, from the control lever or pedal down to the throttle arm. Particular attention should be paid to the spring that retains the throttle in the closed position, because, should this come adrift or break, the throttle may assume the full open position, with disastrous results, unless the driver imnediately realizes what has happened and switches off the ignition.

See Carburetter ; Internal Combustion Engine ; Motor Car ; Motor Cycle.

THRUSH : The Bird. A constant inhabitant of the garden where there is a hedge or bushes suitable as a nesting site, the song thrush is not loved by the fruit-grower, although he has a better reputation than the blackbird. In this connexion, it must always be remembered that the thrush feeds mainly upon worms and snails. The persistent manner in which the latter are hunted and destroyed can be demonstrated by placing a large stone in a convenient spot, and noting how the bird uses it for breaking open its prey; the ring of shell debris around it will testify to the thrush's usefulness.

THRUSH: The Disease. In a parasitic inflammation of the mouth, or thrush, whitish patches appear on the tongue, inside of the cheeks, and also on other adjacent parts. The ailment, which usually occurs in infants, is caused by a fungus. The disease is contagious; that is, it may be carried from one child to another through the medium of bottleteats or spoons.

Mild cases can be cured in 6 to 9 days, the diseased patches coming away and leaving a healthy surface. If the child is sickly and treatment is neglected, the attack may last for months.

Care should be exercised to keep the mouths of children clean, and this is all the more important when they are sickly. The mouth should be cleansed after every meal, so that no remains of food may be left to form acids. In sickness the mouth should be washed 2 or 3 times a day with a weak alkaline lotion, such as lime water, or water in which a little bicarbonate of soda is dissolved, a teaspoonful to $\frac{1}{2}$ pint of water. If the child is hand-fed, the bottle, tubes, teats, and the utensils used for heating the milk should be kept scrupulously clean. The milk must be pure and fresh. Starchy food should be given with the greatest caution before the age of 10 months. If there are any signs of indigestion or acidity of the stomach, add about $\frac{1}{4}$ limewater to the child's milk.

As soon as the spots appear they are to be treated with any of the following applications: Solution of boric acid, 10 gr . to 1 oz . water; or solution of salicylic acid, 2 gr . to 1 oz . water; or sodium bi-borate, 12 gr . to 1 oz . water; or permanganate of potassium, 1 gr . to 2 oz . water. Any of these lotions may be applied with a camel-hair brush, or with a piece of boiled lint wrapped round the end of the finger, or they may be sprayed on the patches of thrush.

THRUSH : In Horses. Horses of every kind are liable to thrush of the feet, which is denoted by a discharge of matter, and is generally due to insanitary conditions in the stable. It is most commonly the horse's hind feet that suffer. Many farm horses get the discase through no drainage being provided. The cobble-stone paved stable is a fruitful cause, unless this has been set in the concrete and is well drained.

The trouble affects the cleft of the foot pad, or frog, as it is called. A frequent cause is through allowing soiled straw, etc., to lodge in the feet, and there remain until it drops out, proper use not being made of the foot picker. The feet should be picked up and cleaned out every time the horse leaves the stable, also whilst it is in the stable. When a horse returns from work it is customary to wash the feet, but care must be taken not to wet the clefts of the frogs and the hollows of the heels.

It is of primary importance to attend to such hygienic matters as a clean dry stable floor, drainage, plenty of straw bedding, and regularity in picking out the feet. Dress the cleft of the frog daily with calomel and pack it
into this by inserting a pledget of tow. This will usually cure it in a few days; but if not, try a lotion consisting of 5 gr . of corrosive sublimate dissolved in loz. of methylated spirit. This dressing, which should be used daily, is applied by pouring it into the cleft, soaking a piece of tow in the solution and packing it into the cleft.

THUMB. The human thumb has a very free range of novement. It may be flexed or bent in on itself, extended or straightened out, adducted or drawn across the palm, adducted or carried out from the hand, and opposed or brought across to touch the other fingers. It is characteristic of paralysis of the median nerve that while the thumb may be adducted it cannot be opposed to the other fingers. The part played by the thumb both in performing fine land movements and in gripping is a very large one, and these functions are seriously impaired in median nerve paralysis.

The ball of the thumb is technically called the thenar eminence. Both this and the hypothenar eminence, the corresponding muscular mass on the inside of the palm, manifest wasting in ulnar nerve paralysis. The thumb is not infrequently dislocated, and great difficulty may be experienced in reducing the dislocation. See Bandage; Hand.

THUMB LATCH. This term is used to describe a type of latch which is operated on one side of the door by the thumb. As a general rule it is similar in appearance to that known as a Norfolls latch. See Latch; Norfolk Latch.

THUMBPIECE.
Known also as the purchase, this is often found on jugs or tankards and other drinking vessels that possess a lid, being placed on or near the handle so that the drinker can raise the lid by placing and keeping his thumb thereon. The two main shapes for the purchase were corkscrew and bifurcated. On a tankard of the 17 th century the thumbpicce is sometines a very decorative feature. On one it represents a pierced heart, cmbossed and chased with Howers, foliage and figures. See Silver; Tankard.

THUNBERGIA. This is a pretty climbing plant for a heated greenhouse. The favourite kind is alata, of which there are several varieties with blooms of various colours. These plants are very pretty when grown in wire baskets suspended from the greenhouse roof. They bloom in summer and are raised from seeds sown under glass in spring ; a compost of loam, leaf-mould, sand, and a little decayed manure suits them.

THUNIA. This is a family of hothouse orchids, about $l \mathrm{ft}$. in height, and with white, yellow, or purple flowers in the summer time. They need plenty of heat and sunshine during the growing season, which is from March till October. At this period plenty of water is necessary. During the winter months, $60^{\circ}$ is sufficient. Propagation is effected by division of the pseudo-bulbs when the plants are repotted in early spring. See Orchid.

THUYA. This is the botanical name of a group of evergreen conifers; the common name is Arbor vitae. They are closely related to the cypress or cupressus and some of them are used to form tall hedges in gardens. One of the most striking kinds is the so-called red cedar (Thuya plicata or Lobbii) which grows into a large tree. Thuya dolabrata from Japan, and orientalis from China, are familiar garden trees. There are several ornamental varieties of the Chinese Arbor vitae (orientalis), e.g. aurea, and glauca with golden and grey-blue leaves respectively, and of the American Arbor vitae (occidentalis). These conifers, which should be planted in SeptemberOctober or in April-May, thrive best in deep loamy soil which does not dry out in summer.

THYME. These fragrant-leaved plants are types of goitre, for mental deficiency in young valued both in the kitchen and the flower- children. and in obesity. See Cretinism; garden ; they like light or well-drained soil Exophthalmic Goitre; Goitre and a sunny place. The wild thyme is Thymus serphyllum, 2 in . high, with purplish llowers: this together with its varieties coccineus, which lias rose-red blooms. the lemon thyme

Thyme. A flourishing plant of the fragrant common thyme, much used as a flavouring in cookery
(citriodorus), and the grey, woolly-leaved in an average temperature of 60-65 degrecs. thyme (lanuginosus) are delightful little plants Propagation is by cuttings of young shoots for the rock garden and paved paths. The taken in springtime and inscrted in pots of dried shoots of the lemon thyme are used for sandy soil. The favourite kind is rutilans, scent sachets and for perfuming soaps. The which bears crimson flowers in winter and common thyme of the kitchen garden is Thymus vulgaris.

Uses in Cookery. Thyme is used in cookery for flavouring dishes. For this purpose it may be raised either from sced, division of old plants, or from cuttings. Seed should he sown out of doors in light soil, in early spring, or cuttings may be made a little later on in the season. The shoots shoukl be collected, tied up in bunches, and suspended in a wellventilated room or shed to dry. See Bouquet Garni ; Herb Garden.

THYROID GLAND. The funstions of the thyroid gland, which is situated in the front of the neck just below the Adam's apple, are very important. It has a powerful inlluence on the nutrition of the tissues of the human body, and on the mental and bodily development. The gland is larger in women than in men, and sometimes reaches an enormous size in goitre. The secretion of the gland contains a certain amount of iodine in organic combination.

In some children the thyroid is very small when they are born. or it may waste in the early years of lifc. These children sufler from cretinism. Sometimes in adults the gland wastes until it almost diappears, and in such cases the disease myxoedema is prolluced. Both diseases result from absence or diminution of the lluid secreted by the thyroil. Enlargement of the gland is a common discase.

Thyroid extract, or the powdered dried gland preparcel from the thyroid gland of nowly killed healthy sheep, is used frequently in the treatment of diseasc. It may be employed in cretinism, myxocdema, certain

THYRSACANTHUS. These beautiful hot house flowering shrubs grow from 2 ft . to 3 ft . in height. They thrive in the usual potting mixture of loam, leaf-mould and sand
nasses, suggesting the creamy-white edges of waves: hence the name foam flower. Propagation is by division of the roots in spring.

TIBOUCHINA. Sometimes called the Brazilian spider flower, this is an evergreen Howering shrub suitable for a heated greenhousc. Macrantha, which is the most suitable for anateur cultivation, forms a large bush and bears purple flowers in winter. It should be grown in well-drained pots or tubs lilled with peat, sandy loam, plus a little charcoal and sand, all well mixed together. It may be trained to trellis, pillars, or walls.

TIC. A muscular twitching of museles, usually the muscles of expression, is known as tic. It occurs most commonly in young girls. It is treated by re-education in the control of the muscles affected. Mimic tic is a more serious condition which generally occurs after middle life. It is incurable.

TIC DOULOUREUX. This extremely severe forn of neuralgia sometimes occurs in the branches of the fifth cranial nerve, also known as the trigeminal nerve. This nerve has threc main branches, one supplying sensation to the eyeball and to neighbouring parts, another supplying the region of the upper jaw, and the third the region of the lower jaw. The pain occurs in paroxysms, at first at long intervals perhaps, but later on al most continuously.

Large doses of quinine are sometimes useful, also such drugs as antipyrin and aspirin. But as they have to be used in large doses, all such medication should be at the hands of a loctor. The application of warmth, of clectricity, of cold, or of anodyne liniments or ointments may afford adequate relief in the mildest eases. Cure, however, can only be secured in one way, and that is by operation. See Neuralgia. Pron. Tik-doo-lo-roo.

TICK : On Dogs. This very noxious little insect is sometimes found on dogs, as it is on other animals. In appearance it bears a resemblance, as far as the body is conecrned, to the spider, and varies in size from that of a pin's head to that of a small pea. In colour the smallor ones are light grey, but they become dark when too gorged with blood.

The tick fastens on the skin, and holds on with such tenacity that the attempt to remove it will often lead to the insect breaking into two parts, when a nasty sorc will usually be left on the affected animal. The insect is found occasionally in the cleanest kemnels and on the best kept animals, as a dog may have come into contact with one that is iafested with it. As soon as ever the tick makes its appearance, steps should be taken to get rid of it. The dog should be treated with one of the preparations that are sold for this purpose, and the treatment should also include the kennel, as the pest often finds a lodging in the wood. See Dog.

TICKING. This very strong limen or cotton material has its chief use in the covering of mattresses, because it is so closely woven that the feathers camnot penctrate it. It is usually twilled, and white in colour, with pink, red, or blue stripes. It is also sometimes cinployed for awnings and tents. S'ee Mattress.

TIE BEAM. In louiding work, the tie heam is the very important member of a king post roof truss or a queen post roof truss, which ties the truss together at the fect of the principal ralters and prevents the truss from spreading.

The tie beam is fixed to the fect of the principal ratters uith the aid of long iron bolts and straps, and it is supported in the centre by a gib and cotter. See King Post; Queen Post; Rafter: Roof

TIE DYEING. This is a form of fancy home dyeing by which very beautiful multisoloured effects can be achieved for lampshade silks, scarves, and short curtains. There is no outfit required heyond thread, wax, and a few brushes and dyes.
Jap silk is one of the simplest materials to use, but crêpe-de-Chine and georgette of good quality also yielrl good results. A little piece of silk is pieked up in the middle of the square, circle or strips and tind with thread which has been dipped in wax. The silk is pulled up again and tied $\frac{1}{2}$ in. lower down, repeating this at intervals all over the piece of silk, and tying once only. The material is dipped into lukewarm water, then into a dyc-bath. When the string is removed the strangest patterns will be found on the silk. Match-ends dipped in wax and placed on the matcrial to form stars, squares, etc., give many variations.

Small portions of the material may be accordion pleated, ticd up, and dipped in wax. This will preserve them, and when the rest of the material is dyed they will remain the original colour of the material. Where several colours are used the material can be ticd at intervals, increasing in size while working outward. Wet the silk, then dip each section into a different colour.

When al! the tying is tinished the material is spread on a piece of damp newspaper, and a large brush charged with colour is used to tap the top of each little tied-up piece. The brush should be charged quickly and the wet material splashed all over, using first one colour and then another. Light shades should be employed lirst, as dark ones are very penetriting. A small brush dipped in either black or brown is useful for making thin lines, which give a cohwehby effect. The material should be kept as llat as possible on the paper, and untied as soon as all is coloured When almost dry it should be irened out.

Good quality dyes naturally give the best and most permanent results, those sold for Batik being excellent. Fixing acid, acetic acid, or vinegar must be added before dyeing is commenceil. See Patik: Dyeing.

TIGER FLOWER. This is a brilliantly coloured bulb Hower which needs rather sperial treatment. They should be planted

Tiger Flower. Brilliartly coloured flowes of the Peacock type, suitable for a sunny border

3 in . deep in March in a well-diained border of sandy loam in a sheltered sunny place : it is wise to set the hulbe on sand. In autumn they should be lifted and stored in sand for the winter. If grown in pots the bulbs are potted in autumn or winter, placed in a frostproof frame until top growth appears, and then brought in the greenhouse. Great care
must be taken not to give much water until the bulbs are well rooted.

The peacock tiger iris (Tigridia pavonia) is the favourite kind; there are varieties in gorgeous shades of colour. Conchiflora, yellow and scarlet, is another handsome sort
TIGER LILY. This is one of the best hardy lilies for amatcur gardeners. It reaches a height of about 4 ft ., and hears orange-red llowers in August and September. The bulbs should be planted 5 in. deep in autumn or spring in wel! dug soil with which leaf-mould and sand have been mixed freely: they may be left undisturbed for years. The linest varietics are Fortunei giganteum, and splendens, with flower stems 5-6 ft. high and orange-scarlet Howers. See Lily
TIGER MOTH. This describes the garden moth, whose caterpillars air known as woolly
bears. The caterpillars feed on flowering plants and vegctables. The parent moths may be identified by their red and black bodics, brown and cream forcwings, and hind ones of purple, red, and orange. Destruction of the moths and hand-picking of the caterpillars are the only effectual remedies.
TIGER WARE. This ware was used for a certain type of jug made chicfly in the l6th century, and now much sought by collectors. The ware is a dark, mottled pottery, very hard with a finc glaze, and the jugs are often silver mounted. The style has been much imitated by modern makers. One example, dating from 1559, is mounted with neckband, cover, and foot of silver gilt; the neckband is engraved with foliage and strapwork, and the cover embossed with fluting. The thumbpiece is fruit-shaped.

## Tiles and the Process of Tiling

Protective and Decorative Uses Described and Illustrated
This contribution is conceraed with a number of s ructural and other matters, both in house and garden. on, which there are entries in this work. Such include Bathroom; Bungalow; Cotage; Garage ; House ; Kitchen: Path; Roof; Sink. See also Concrete; Floor ; Mosaic ; Pantile: Rubber, etc.

A tile is a comparatively small and thin piece the section shown, it is moulded so that the of haked clay, made in substantially the same overlapping part fits into a grooved portion way as bricks. Such tiles are extensivcly on the tile beneath it
used for roof coverings, wall surfaces, floors, and other purposes. Glazed earthenware tiles are used where an impervious and cleanly wall covering of a more or less ornamental character is needed, and for fireplaces.
The largest class of tiles consists of those emploved for roof covering. Hand-made rooling tiles are noted for their good colour and surface. As a rule they weather better than the machine-made variety. Machincmade tiles are genera!ly harder and more homogeneous, more uniform in colour and texture, and more regular in shape. They are made by processes similar to those used in making bricks, but the matcrial is more carefully graded.

Much of the charm of the small English home is due to the use of the dark red sand faced tiles. This is especially the case with old tiles, to which time has imparted warm tints often relicved by traces of moss and lichen. Apart, however. from their picturesque appcarance, tiles form an extromely durable roofing material; many houses with tiles over 100 years old are as weatherproof as when they were first roofed.

The colour of British tiles ranges from warm reds, browns, and strawbery colours to tints of bluc, gieen, and grey. Among the earlicst tiles are those known as pantiles, a flat $S$ shape, averaging about 14 in . in length, $9) \mathrm{in}$. in width, and in. thick. Onc colge of the common pantile is turned down rather more sharply than the other, and this edge overlaps the Hatter edge of the neighbouring tile (Fig. 1). The projecting nib which rests against the roof batten is shown in the section bencath.

A development of the pantile has been evolved by different makers. Some of these tiles are of considerable sizc, and are flat for the major portion of their area. Onc edge is sharply upturned, and the other is more or less scmi circular in shape. A rooting tile of the intcrlocking type is illustrated in Fig. 2. As will be secn by

By far the greater number of tiles for roofing are of the so-called flat type (plain tiles) illustrated in Figs. 6 to 12. Of these there are many kinds, varying in colour, density, weight and durability. Choice is largely a question of price and effect. The chcapest are a bright red in colour, and machine made. The average size of the plain tile is 10 in . long, $6 \frac{1}{2} \mathrm{in}$. broad, and about $\frac{1}{4} \mathrm{in}$. thick. On the average, about 650 tiles, weighing $1 \frac{1}{2}$ tons, are needed to cover a square, that is, 100 sq . ft. of roof area.

Plain tiles are made in three widths, known as half-tile, tile, and tile-and-a-half tile. The two latter are used as end tiles in alternate courses, so as to break the joints, that is to say, so that there should not be a continuous series of vertical joints in the roof covering. In some cases, half-tiles cannot be fixed satisfactorily, and it is customary to use a tile-and-a-half tilc, which has the same effect in breaking the run of the joints. The plain tile is rectangular, and there are fancy or shaped varieties for decorative purposes. such as a few courses of bandings or fancy patterns introduced as a varicty in a large roof arca. Similar tiles employed for covering walls are known as hanging tiles.

The ordinary plain tile is not perfectly flat. but is curved in the direction of its length and across the breadth. Consequently, the upper surface is slightly dome-shaped, which ensures the water draining off the surface. For fixing purposes, tiles are made with small projecting nibs on the top end edge ; and two small

$$ conveniently near to the sccne of operations.

The lirst step in the actual laying of the i.iles is to have the roof prepared for their reception. They can be laid directly on to the battens, or the roof may be covered with rough boarding with tarrod felt over it, and hattens upon which to set the tiles. The battens must be perfectly horizontal and laid at the proper distance or gauge from each other. The meaning of the expressions lap and gauge, as applied to plain roofing tiles, is made clear by the diagram, Fig. 7. From this it will be seen that the gange is the distance lictween the top edges of two hattens and the lap is the amount by which one tile overlaps the tile on a course next but one below it.

For completc protection, it is necessary that at any given point there should be three tiles. The ronf remains weathertight not because the surface is sloping, but because the tiles overlap each other. Owing to the triple lap. any water that penetrates the outer layer of tiles will le deflected by the lower layers.

Ordinary tiling is commenced at the caves, and preferably at the right-hand end or verge. A scaffolding is required, and it should be placed so that the worker stands about 2 ft .6 in . from the caves line. The first step is to lay the eaves course, made of special tiles, which are about threc quarters of the length of the ordinary tiles. These are inclined at $n$ differeni angle to the rest of the roof, rather Hatter than the remaining courses so as to tilt up the lowest course, this tending to make the roof drier. A fow are laid as a start.
The next step is to commence laying the first course whose lower edges coincide with those of the eaves course (Fig. 8). These are rested with their nibs on the upper cdge of the batten, and the first few tiles may be further secured by means of galvanized iron nails, about $1 \frac{1}{2} \mathrm{in}$.
should be sprearl over the tops of the eaves tiles before fixing the first course, so that the latter is bediled in mortar.

After the first fow liles of the first course have been laid, a tile-and-a-half tile is set on the second course, commencing from the verge as before, and bedded in mortar. The tile is gently tapped down so that it rests firmly on the tile heneath it, by lightly tapping upon it with the end of the trowel handle, as in Fig. 8. Several more ordinary tiles are then laid on the second course, but thesc will not need to be bedded in mortar. The third course is commenced, the first tile being bedded in mortar and the edges brought up level with those beneath it. The next course is then continued, and the worl: goes forward, gradually working along and up the roof until the ridge is reached.

To save labour and the time of constantly clambering on and off the roof, an assistant can stack the tiles by resting them between the battens with others at right angles to them, as shown in Fig. 9. Thus the tiler is supplied constantly with tiles, conveniently placed

It is desirable in exposed positions to nail about every fourth course by driving $1 \frac{1}{2}$ in-

Tile. Fig. 8. Setting the tile-and-a-balf tile for the start of the second course
galvanized iron nails through the lioles in the tiles. It is not necessary to nail every tile except in very exposed districts. If half tiles are used instead of a tile-and-a-half tile, they are set in place in exactly the same way. Should there not be enough of these, ordinary plain tiles can be cut in half by scoring a line along the centre and cutting them with a sharp blow from the edge of the trowel, cutting downwarl rather than across the tile.

The appearance of the verge or end of the roof when it is completed is shown in Fig. 10, which also indicates a simple method of finishing the tiles around a chimney stack with strong cement mortar applied round the sides of the stack and on top of the tiles. This is not necessary when tlashings are fitted, as thesc come on the tops of the tiles and keep out the wet.
The ridge tiles are set on the apex of the roof and are merely bedded in strong cement mortar. Hip and valley tiles are worked where requisite at the junctures between roofs which meet at an angle. In another method a valley gutter is often formed with lead set upon valley boards, and the tile courses terminated with the tiles cut diagonally. A detail of this class of work is illustrated in Fig. 11. To support the tiles where they overlap the gutter a continuous batten or ridging is necessary to raise them above the surface of the gutter. Usually, however, the vallcys should be worked
with the proper valley tiles which course and hond with the plain tiling, or the tiles may be swept and laced, as illustrated in Fig. 6. A valley board about 9 in . wide is laid up the valley, and the tile courses are continued from the two intersecting slopes of the roof, so that each tile on the main part of the roof overlaps a tile on the subsidiary part. Alternatively, the courses from cach slope may be taken over and under in alternate courses. The last tile of every course, of which only the corner will show, is preferably a tile-and-a-half tile. Tiles can only be laid in this way when one roof is subsidiary to the other, otherwise the ridge line will be broken.
At the verges, the finishing may be by close tiling, that is, the tiles project only from 2 in . to 3 in . bevond the gable wall, and are given a slight inward tilt to throw water away from the edge. Alternatively. a projecting varge and a bargeboard ean be adopted, the cnds of the tile courses being pointed with strong cement mortar.
Tile Hung Walls. Vertical tile hanging is a method of covering the surfaces of walls in exposed positions, and it forms an excellent protection. The method is shown in Fig. 12. The groundwork is often composed of horizontal battens of wood nailed to the brickwork The objection to such a plan is that the timber is liable to rot and decay, but it is often the only practical plan. The tiles are hung on straw. These are beaten down comparatively

Tile. Fig. 9. Showing bow to stack tiles on rafters ready for use. Fig. 10. Verge with tiles in place and cement fillet around chimney stack. Fig. 11. Tiles cat to form simple valley gutter. Fig. 12. Showing bow lowest courses of tiles on a tile-hung wall should be tilted
hollows and grooves are overlapped, the gauge being about $4 \frac{1}{2}$ in.
Doubling courses of tiles are used under the roof eaves, and also on the lower courses, and above any openings. The tiles are given a considerable local upward tilt, as in Fig. 12 to throw the drops of water clear of the window. sill or opening beneath it. Fig. 13 depiets a small cottage tile-hung with dark red, sand. faced tiles of ornamental pattern. A method known as Winchester underhang is illustrated on page 1077.
Ordinary plain tile roofs should have a pitch of about $45^{\circ}$ to $47 \stackrel{1}{2}^{\circ}$, and be rather stceper in exposed positions. Apart from the tiles already mentioncd, there are others specially shaped and adapted for particular purposes. Glass tiles arc built into a roof to help to light the intcrior, and there are various fancy shaped and special purpose tiles. The repair of tiled roofs usually consists of raising the tiles in the vicinity of those which are damaged, pushing them upward and lifting them over the battens, replacing them in a similar manner with new tiles. In all such roof repairs, the use of a proper roof hoard or some adequate method of protecting the tiles from breakage is of paramount importance, otherwise more damage is likely to be caused. One plan is to rest a light ladder upon two large sacks filled with nibs and each is acparatcly nailed. The flat before they are rested on the roof, and

Fig. 13. Atlractive effect of a cottage tule-nung with dark red sand-faced tiles of an ornamental pattern
act as a soft pad between ladder and the tiles. The amatcur should attempt only the simplest replacements (c.g. to a low roof, such as that of an outbuilding). The builder uses a special "duck" ladder, which is securely fastened at top and bottom. Apart from the likelihood of the amateur damaging the sound part of the roof, there is considerable personal risk in work carricd out on a bigh roof.

Decorative Tiles. With the advance of hygienic wisdom in the home glazed tiling for kitchen, scullery and larder is bocoming more general. Though other suitable mural coverings are somewhat less expensive tiles are worth the extra cost where durability, elcanliness and labour-saving are the first considerations; also they do not depreciate in wear. The advantages of tiles in the bathroom are obvious and the scheme is sometimes completed by a tiled floor. Where paint is used for the walls, inset tiles form an excellent splash back for the bath and lavatory basin.

British glazed tiles are uncxcelled in qua!ity, colour and designs. Fine decorative mural tiles are made of glass as well as of clay. The glass has a matt surface, is semi-opaque and can be obtained cither stained in plain colours or painted with pictorial designs. Use is mado of these for inset borders and wall panels.

The depth of the glaze of carthenware tiles varics with the style of the design. In some cases this is in relief, in others it is painted, while a third class of tile depends for beauty only on its fine monochrome glaze. In choosing tiles for a hearth and fireplace, should a pictorial pattern be required, only good designs should be considered, as cheap ones are unpleasant to live with and plain tiles of barmonious colouring are preferable.

These tiles are generally small and square, varying from 3 to 6 in . in size. They are laid in a similar manner to llooring tiles on a concrete hed with plaster or mortar. Generally when a tiled fireplace is purchased a hearth is laid to match, and tiled curbs are obtainable.

Simple Tiled Work. If it is only desired to half-tile a wall, the joint between tiles and plaster wall face is made with a simple wooden moulding. A tiled sink back is invaluable in the kitchen of a sinall flat. Tiles of a suit. able character can be obtained from the better-class iroumongers and may be set in place against the wall with a good breking of plaster. especially when the tiles will fit
under a window ledge. A proper key must be provided to the brichwork of the wall, as describerl in the articles on Cement and Rendering. To avoid the difliculty of cutting the tiles to the slope of the draining hoard, the latter can be reinoved, cut back a little, and refised. The joint between the sink top and the tiles is preferably made with strong l'ort land cement mortar. The tiling of large arras is hardly a job for the home worker, and the services of an experieneed workman should be obtained for this.
Tile Paper. This term is used to deacribe wallpaper the surface of which is printed to represent tiling. See Wallpaper.
TILLANDSIA. These are hothouse erergreen plants with large, strap-shaped, green or coloured leares and coloured bracts. They flourish in pots in n well-drained compost of loam, with which sand and brokun brick are mixed, and are propagated by detaching and potting the suckers or offshoots in spring. Lindeni and splendens are two of the best sorts

## TIMBALE: In Cookery. Rich and

 saroury mixtures of meat or fish, such as scallops of chicken, small birds, game, !ohster or oysters may be served in the ornamental case known as a timhale. The case may be composed of macaroni, spaghetti, or even of aspic, but the slape is invariably round and it is usual!y cooked in a special mould.For a macaroni casc the large variety should be used. This must be boiled with stock and then cut into $\frac{1}{2}$ in. lengtles. A plain, buttered, round mould with a rounded top should be used, and the pieces of macaroni so arranged that they line the whole inside of the mould standing on end. Over these a layer of forcemeat is placed, and the surface of this is smoothed with a knife dipped in hot water The forcemeat is necessary to prevent the portions of macaroni from sljpping. The mould is then filled up with a savoury mixture and steamed.

Any mixture of cold meat, game or poultry is suitable for filling the timbalc. The proportions are as follows : $\frac{3}{4} \mathrm{lh}$. cold coolied meat, chopped small, 2 oz. white beadcrumbs, 1 oz butter or dripping, 2 egges, 1 dessertspoonful chopped onion, half teacupful stock, 2 teaspoonfuls chopped parsley, $\frac{1}{2}$ pint brown sauce, salt and pepper.

Melt thic butter in a saucepion, add the onion, and fry lightly, then remove it and mix with the meat, crumbs, and parsley Beat the eggs, arld the stock, stir into the rest of the ingredients, season well, and be sure that all the ingredients are mixed smoothly and evenly. Put the mixture, a little at a time, carcfully into the lined mould, and press in gently but firmly. Twist a piece of greased paper over the top, and steam the timibale for half an hour.

Take off the paper, and turn out the 1 imbale carefully on to a hot dish, and strain the hot brown sauce around it.

Beef Timbales. Timbales made from spaghetti and cooked bcef can be prepared thus Brak 2 oz. spaghetti into small pieces, wash it, and then cook it in a pan of boiling water until it is tender. Grease some sınall, plain moulds, and line the sides and hottoms with some of the strained spaghetti, pressing it well to make it adherc. Then fry a peclerl and chopped onion and a chopped mushroom in 2 oz. dripping. Mince 6 oz . cooked beef previously freed from skin and bone, and add to it 3 tablespoonfuls breadcrumbs, 1 teaspoonful chopped parsley, the cooked onion and mushroom. Mix well, add salt and pepper to taste, ahout $\frac{1}{2}$ gill brown gravy, and a beaten egg. Put the mixture into the prepared moulds, cover it with the remaincler of the spaghetti and tie a greased paper over each. Steam the timbales for about 30 min . and, when they are almost cookerl, fry 4 tableapoonfuls freshly cooked or bottled runner
beans in 2 oz . butter. Turn out the timbalcs carcfully on to a hot dish, pour a gill of hot brown gravy round them, and use the beans as a garnish.

Fish Timbales.
These are usually made with an aspic casc. Turbot, halibut, or any firm white fish may be used. Salmon also is good in a timbalc. To make, pound some of the cold cooked fish with enough stiffened white sauce to moisten it, adding seasoning to taste: then line the inside of a large timbale mould with some melted aspic jelly. When it has set, mask it with the pounded fish and fill up the centre with some flaked fish, also moistened with white sauce to which has been added some cream and a little piquant flavouring. Put a layer of the pounded tish on top, and İeave the whole to set. When quite firm, turn it out of the mould on to a dish and garnish it with chopped jelly and salad.

TIMBER. The trunk and larger limbs of trees are usually known as timber after they have been felled and stripped of the outer covering of bark. Timber trees are those which can be used for general building or wood working purposes, and they are classilied into two groups, conifers and broad-leaf trees. Examples of the former class are northern pinc, producing yellow deal; Pinus strobus, producing yellow pinc; Larix europaca or larch : and Pinus rigida or pitch pine. Of the latter class, oak, ash, lime, and sycamore are examples. There is also a sub-division into hard and soft woorls.
Timber trees which have reached maturity are felled during the autumn and winter, when the sap is more or less dormant. The timber has then to be seasoned, during which process it shrinks and drics; it is then converted to suitable sizes, and further seasoned prior to use. The newly felled trec is called a log; when trimmed it is known as a ba!k. When sawn, the various sizes are known as deal, plank, board, batten, scantling, and quartering. See Beech; Deal; Grain: Mahogany; Oak; Wood, etc.
TIMING: For Engine Speed.
power which is developed by any type o internal combustion engine will depend entirely upon the correct timing of the ralves and the ignition, assuming that the compression, carburation, and sparking plugs are in order.
To deal first with the valves, there are four phases in the cycle of their opcration, namely, induction, compression, explosion or power stroke, and exhaust. Not less than two valves per cylinder are required, one controlling the inlet of the fresh gases, the other the exit of the burnt gases: these are known respectively as inlet and exhaust valves. They are timed througl the medium of the camshaft to open and closc at the correct moment of piston position.
The greater the speed of the engine the earlier must the inlet valse open, and re. main at its full open position until the piston has just. started on the up stroke. The object of this is to give the gases the maximum of time in which to enter the eylinder. Owing to the continuity of direction or flow of the gases, the fact that the crankshaft has just passed the bottom dead centre and is about to start the piston on the up stroke is not felt by the gases until well

Tining. Fig. 1. Showing diagrammatically some examples of chain driven timing gears
after the inlet ralve has closed, thus allowing the compression stroke to take place.

Meantime the exhaust valre is closel, and it remains closed until the piston has descended to within approximately $\frac{1}{A}$ in. from the bottom of the power stroke at which point it opens, and does not again close until just before the top of the stroke is reached. This period is termed the exhaust stroke. Immediately the exhaust valve closes, the inlet valve opens. Sometimes the timing of the valves overlaps, i.e. the inlet valve opens just before the exhaust valve closes. Especially is this the case with the high-speed engine.

A timing diagram is given on page 812, and should be read as showing average timing only In all cases the timing diagram issucd by the makers of the engine should be strictly adhered to. Timing gears being positivels driven and contained within the crankcase are protected from any chance of derangement other than a fracture of the parts involved.

Before dismantling a timing gear the setting should always be noted careful!y In most cases marks will be found at the root of a tooth of one wheel that clenote its position in relation to corresponding marks on the wheel with which it is in engagement. These marks should be brought together and a reference made of piston position, i.e. make absolutely certain whether the timing is marked for the commencement of the inlet stroke or the exhaust stroks, as makers are not all in agrecment on this point.

Accuracy in re-asssmbling is essential if untoward consequences due to back-firing are to be avoided. If the amateur is not confident of his ability to re-time correctly he will be well advised to employ expert help.
With multi-cylinder engines the periphery of the flywheel is sonctimes marked to show the top and bottom dead centre of the crankhaft, with adiacent marks reading inlet and exhaust, to show the point at which the respective valves open.

Timing Gear. All timing gears for fourstroke engines lave a two to one reduction, i.e. the crankshaft makes two complete revolutions to one revolution of the camshaft the ormer drives. The two types of timing gear in common use are the spur cog-wheel drive and the silent chain drive. The silent chain drive may be carricd out in three ways as shown in Fig. 1. The simplest arrangement is that depictel at $C$, one chain embracing the three sprocket wheels; by varying the position of the magncto sprocket, which is fitted on a separate bracket, the whole of the gear is adjusted.

The arrangement shown at A employs two chains. The magneto chain can be adjusted by the means described for C , but it is only possible to keep the camshaft chain at a uniform tension by fitting a spring-fed jockey sprocket wheel, as shown. In most cases where two separate chains are employed, the arrange-
ment is as shown at B, with the chain adjusiment the same as at A.
The gear-whicel clesign of timing gear as commonly employed for multi-cylinder car engines is shown at A (Fig. 2). With a view to sitence in operation, skerp or helical gears are frequently used, and very olten the large whicel which drives the camshaft is formed of vulcanized fibre, supported on both sides by a disk of phosphor bronze. The timing
gear for the overhead valve is often identical in principle with long tappet rods, but fitted to connect from the cams to the ovcriead rocker arms. An alternative arrangement is the positioning of the camshaft as a part of the detachable head, i.e. the detachable head. valves, rocker arms, and camshaft form a complete unit. With this arrangement the drive to the camshaft is either by silent chain or some form of toothed wheel drive, transmitted to the canshaft by means of it vertical shaft that in turn is driven off the crankshaft. Since the timing gear is disturbed each time the cylinder head is removed in the process of decarbonizing the engine, careful note should be made of the timing marks on the wheels.

Sometimes the camshaft is connected to the drive of the vertical shaft by means of a disk coupling that is provided with a location stud, thus ensuring the correct timing of the vaives when reassembling the unit. With this design the removal of the detachable head in no way interferes with the timing gear.

Timing the Spark. Of equal importance is the timing of the ignition, whether it be by magneto or by the coil and distributor method. The two systems in common use are known as the fixed and the variable. With the former the spark should be set to occur just before the piston reaches the top of its stroke. J3y this arrangement the crankshaft has crossed the top dead centre before the full force of the explosion is felt. No definite rule can be laid down for this setting, because the actual amount of lead given will vary with different types of engine. On an average the platinum points of the contact-breaker should be set to part just when the piston is still within approximately $\frac{1}{\frac{1}{3}} \mathrm{in}$. from the top of the compression stroke. With variable ignition the platinum points should separate at the top of the stroke, with the control lever for the ignition at the full-retard position. By so doing, on advancing the control lever the spark occurs earlier.
The time taken by the gases to reach a state of complete combustion is always the same. Therefore, at high engins speeds the spark must occur proportionately earlier, so as to assure complete combustion by the time the piston is starting to travel downward on the power stroke. As engine speed decreases the spark must be retarded, otherwise a pronounced knock will be manifest.

Although with coil and distributor ignition the same end is attained, the method of control is entirely different. The usual procedure is to rotate the distributor about the wipe contact, thus causing the wipe to make contact with the segments of the distributor either early or late in relation to the positions of the piston. See Magneto; Tappet; Valve.
TIN: The Metal. A white, soft, and malleable inetal, tin is not used to any extent by itself. Owing to its softness and ductility it is easily worked, and articles made from it can le finished with a brilliant polish, but the surface is easily scratched and bruised. It is considerably used as an nlloy, and it readily combines with copper, antimony, bismuth, zinc, and lead. Tinman's solder is composed generally of equal parts of tin and lead. When hardened with a small amount of

Timing. Fig. 2. Diagrammatic examples of cog-wheel

copper, tin forms the best pewter, and although it is often combined with lead for the same purpose, the result is not satisfactory. Bronze is formed with a larger proportion of copper than that used in pewter T'in is employed for conting iron and copper vessels used for cooking pur poses, in the latter case to prevent the poison from the copper getting into the food.

The most con. siderable use to which tin is put is in forming a protective covering for thin sheet iron which is comnionly known as tin, but correctly described as tinplate. It is also used on iron wire and small articles made of iron. So long as the protective coating remains intact the iron is prevented from rusting. See Tinplate.

TIN LIFTER. A kitchen utensil used to take hot tins and dishes from the oven, a tin lifter somewhat resembles a pair of pliers in appearance, and has the same gripping action. If kept in a convenient place near the stove, it does away with the necessity of an oven cloth, and protects the hands from minor burns.

TINNED FOOD. Tinned or canned foods, if they are properly handled and stored, will keep longer and better than any other class of preserved food; in fact, certain goods, such as salmon and sardines, improve with kecping. Some classes of foods, however, should only be kept about a year; these are fruits canned with the stones, such as cherries and plums, and all classes of fruits and vegetables which contain acid in fairly large proportion, such as apples, pineapples, tomatoes and asparagus.

Tinned shellfish is liable to discoloration by reason of the large proportion of natural phosphate contained in it. To overcome this difficulty, such fish as lobsters, crabs, crayfish, prawns, etc., are now wrapped in heavy vegetable parchment paper, and as a result can be kept much longer than formerly.
Glass containers are also used for preserving foods, and much thought and care has been exereised in producing caps which will form a reliable airtight seal. The practical advantages attached to cans are that they arc casier to handle in the factory, are less fragile, weigh less and are more cconomical as regards transport costs.

Improved Containers. Onc of the greatest improvements in the canning industry of recent years is the introduction of a tin commonly called the sanitary tin. In this the use of solder is entircly eliminated, thus doing away with the danger from the acid of fruits acting upon it. The side seams are locked and lapped, while the ends are stamped out of tin plate and edged with rubber solution. The bottom is attached by means of a double seam, and the same process is gone through after the can is filled. Further improvement in canning has been attained through lacquering the inside of the tin to kecp the contents a natural colour, for such products as fruit, crab, lobster, etc.

Examining Food. The public are protected by the examination of all imported canned goods at the port of entry. The inspectors, acting under the local authority, examine each consignment. As it is impossible to open every case and examine each can, they
take a percentage of the consignment, which is usually about 10 per cent, and carefully inspect these. If it is found that only a small perosntage of cans are "blown," or otherwise unfit for food, the cargo is passed. Should the percentage of doubtful tins prove large the whole consignment is thoroughly examincd. Further examination of tins is periodically undertaken at the shops.
In case some cscape the vigilance of the food inspectors the following may prove helpful. "Blown cans" and "swells" are tins in which certain organismis have not been killed; they develop in the food and form a gas, which causes the ends of the tin to swell out, or become convex. Such tins, when tapped with the fingers or something hard, give off a "drummy" sound instead of the clear resonant note of a perfect can. These should not be used, as in all probability the food is unfit for human consumption. In all cloubtful cases, if the tin has only just been bought, either return it to the retailer, or submit it to the local food inspector, or medlical officer of health, for his opinion. See National Mark; Sardine, etc.
TIN OPENER. A strong and really adequate tin opener should be included in cvery kitchen outfit. The commonest type has a sharp blade for cutting, with a projecting spike bencath. The latter is used to knock a hole in the side of the tin. The blade is then inserted, and the cutting done all round the edge of the tin. The tin opener must be kept clean and free from rust.
Sardine tins are usually supplied with a key opener, which, when turned, rolls back the top of the tin. These are often unpractical and resort has to be made to the ordinary opener. In opening tins, care should be taken to see that the cutter does not slip, for cuts caused by the jagged edge of a tin often result in blood poisoning.

TINPLATE : How it is Worked. Tinplate is a shect of iron or steel coated with tin on cither side. It is commonly made in two qualities or varieties, known as charcoal and coke brands. These names originated when tinplate was made from charcoal iron for the better quality plate and coke iron for the inferior grades. The distinguishing names are retained, but now represent the depth and finish of the tin coating.

Coke plates are largely used for can construction. For conimercial tinplate a common proportion of pure tin to the sq . ft . of plate is $\cdot 023$ or $\cdot 024 \mathrm{lb}$. Tinplates are made in sizes measuring 10 in . by 14 in ., and also in multiples of these sizes for larger work. The sizes most commonly used measure 20 in . by 18 in . and 20 in . by 14 in

The thickness of tinplate varies to standard commercial sizes, mensured in Stubbs' wire gauge. The thinner gauge plates are known by the table of weights and gauges berewith :

| Designation | Gauge | Weight per <br> sq. i. |
| :---: | :---: | :---: |
| 56 lb. | 38 | 0.257 |
| 7.5 | 34 | 0.345 |
| 100 | 30 | 0.459 |
| 130 | 36 | 0.803 |

Tinplate is often called block tin or simply tin, but these appellations are erroneous. Tinplate in which a certain amount of lead is added is known as terneplate, and consists of soft sheet steel plates coatcd with a tin-lead alloy, of which a common alloy is made with $\frac{1}{3}$ pure tin to $\frac{2}{3}$ lead. This form of tinplate has considerable rust-resisting properties, and is used in roofing work. For this reason it is also known as roofing plate. Terneplate is manufactured in the same sizes as tinplate

Tinplate lends itself to the construction of many articles to be found in the household.

a large tinplate box. Tinplate is useful for repairing utensils, as for example in mending a leaking kettle. watering-can, etc. When an acid tlux is used all traces should be washed away or the surface will be corroded. A domestic utensil should be boiled out, or washed out with boiling water and well rinsed beforc using. See Soldering.
TIPSY CAKE. This wine flavoured cake can be made with a tower shaped sponge cako which should be at least 24 hours old. Cut the cake into thick horizontal slices and spread these with apricot jam. Return them to the

A sharp pair of tinman's snips should be used for the amateur is to for cutting the plate, and the amateur may find it an advantage to wear an old pair of gloves, as it is very easy to cut the hands on the rough and aharp edges of the material. In cutting tinplate, care should be taken to keep the tin free from scratches or buckles.
How to Bend Tinplate. In order to bend it, the tinplate is smoothed round cylindrical former where a uniform curved surface is required. Care must be taken to avoid too sharp a bend in one particular place. The whole length of the shcet should be held, and the bending process not localised to one edge of the shect. In bending the shect into a curved surface the most difficult part will be found to be the ends of the material. The commencing end should first be bent to the required radius, then the main body of the sheet.
The operation of bending a sliect of tinplate to a cylindrical shape is shown in Fig. 1 Where an article of conicul shape is required, a correspondingly tapered former should be uscd the tinplate being first marked out to the correct shape. The risk of wasting the material by incorrect cutting may be obviated by marking and cutting a shect of atiff brown paper to the size required. If this is found to be correct, the paper may be pasted on the tinplate or the tinplate marked off from the paper. Before cutting, allowance must be made for the seam or method of joining. Where a soldered joint is to be made on!y a slight overlap will be required ; it is known as a simple lap scam.

Further strength is iniparted to the joint hy means of the grooved scam. This is illustrated in construction in Fig. 2, where the edges are turned up on opposite sides of the tinplate to form a hook when the ends are brought together. After the ends of the cylinder have been folded together the scam is hammered flat by inserting a bar to the inside of the tube, on to which the seam rests during the hammering process. In allowing for the sean in marking out, three times the width of the single turned-over edge should be allowed. If the joint is to be watertight the seam must also be soldered. An easy method of turning over an cdge or lip is illustrated in Fig. 3. where a straight strip of metal is held against the bend while the lip is hammered flat to the top of the strip.
Where it is required to fit a bottom to a cylindrical object in tinplate several methods of fitting are utilized. Probably the most simple
for the amateur is to
cut a disk of tinplate fitting exactly inside the bottom of the cylinder or contsiner. When in position, the work is turned upside down and the bottom soldered in place. Further to securc the bottom a ring of brass or similar wire is fitted to the inside of it and soldered in position.

Where the cdge of a tinplate article is left exposed, it can be bent must be allowed for the wiring of an edge.

Tinplate articles can be purchased so cheaply that it is not worth while to make such things as a kettle, or coffee-pot, which are seamed by machinery and shaped in a press. However, little toys call often be made up from odd pieces of plate or even from material got from
round a wire to form a smooth and neat original shape of the cake and place it in a glass clging, as in Fig. 4. This can only be accom- dish. Half a bottlc of sherry is usually pourcd plished successfully when the sheet is in a flat over it, but the quantity varies according to state, and it should be done in an carly stage. the size of the cake. Baste it at intervals with As in the case of a lapped seam, extra metal the wine which runs from it, and when quite

Tinplate working. Fig. 1. Bending to a cylindrical shape. Fig. 2. Closing a seamed joint, which is made by turning up the edges on opposite sides Fig. 3. Turning over a straight lip. Fig. 4. Forming a neat edge to a sheet of tin by working it round a wire dish. Half a bottlc of sherry is usually poured
over it, but the quantity varies according to soft stick all over the surface splinters of sweet almonds which have been blanched and dried, without colouring, in the oven. Pour over all a cold, thick rich custard and decorate the lase of the cake with littlc heaps of stifflywhipped cream, glace cherries and angelica. See Blanching ; Trifle.

## Tires: Their Use, Care and Repair

## How Motorists May Avoid Expense and Danger

Too often the car owner is content to see that his tires are not visibly slack. If he will follow the hints and suggestions given here he will find that a minimum amount of regular attention will sceure him from any serious tire trouble. Sec also Bicyele; Motor Car; Perambulator:

Puncture
The wheels of all vehicles have special outer the modern pneumatic tire consisting essentiwearing surfaces or tires, whether they are ally of an elastic rubber tube containing comthe flanged steel tires of railway vehicles, the pressed air, and a protective outer cover or steel tires of horse-drawn velicles, solid rubber casing of flexible rubber rendered practically tires, or the pneunatic tires used on bicycles, unstretchable by cotton reinforcement cm motor cycles, and motor vehicles. Only the pneumatic tire need here be considered in detail.

The high comforte drivig speals of modern modern motor vehicles would hardly be efforts between the wheel and the road. It possible without pneumatic tires, which will fail to achieve these objects unless inflated cushion the innumerable minor inequalities to the proper pressure. When so inllated the of the roads and co-operate with the ordinary suspension springs and with the upholstery springs to reduce the effect on the passengers of the more serious road defects.
The original cycle tire invented by Dunlop consisted of an endless inflated rubber tube fitted in the wheel rim. From this has evolved
bedded in the rubber.

In a pneumatic tire compressed air is utilized to support the weight of the vehicie, to absorb air forces the cover outwards with a uniform pressure of so many pounds per square inch, and the part in contact with the road is flattened until the total pressure exerted by the air from the insicle of this flattened area equals the load carried by the tirc. The higher the pressure the smaller is this flattened area.

Tire. Fis. 1. Rim for beaded tire. Fig. 2. Straight side rim with flat base split trausversely. Fig. 3. Straight side rim with flat base and detachable flange. Fig. 4. Well base rim for straight side tire

All tires are either of the beaded edge type of coarse woven fabric, with the strands or the wired (straight sided) typc. Practically all modern cars, motor cycles, cycles, or aeroplanes are fitted with tires of the second type. Very large numbers of beaded tires are still in use, but this type of tire is rapidly becoming obsolete.
The beaded tire is fitted on a special rim having inturned edges or clinches, as shown in Fig. 1. Each edge of the tire is made with a hook or bead which engages under the clinch and has a core of hard ruhber. The bead can only be placed in position by stretching it over the clinch, but is nevertheless too elastic to remain on the rim except with the aid of the internal pressure, which forces it into the clinches of the rim and thus holds it firmly in position. If the pressure is seriously reduced the beaded tire, unlike the wired tire, is liable to be forced off the rim by lateral pressures when the vehicle is swerving or cornering.
The straight-sided tire, on the other hand, has no beads. The edges are reinforced by several strands of steel wire which render them practically inextensible, and the rim is also of entirely different design. Three forms of rim suitable for straight sided tires are in use, namely: The llat hase, split transversely (Fig. 2); the flat hase with one fixed and one detachable flange (Fig. 3); the well base (Fig. 4). The first type has rarely been used on British cars, since the rion is necessarily detachahle from the wheel, but it has found much wider application in America.

In the second type of rim the detachable flange is sprung into a groove on one side. The flange can bc detached by using a lever, and the tire may then be removed sideways without much difficulty. This form of rim is largely used with heavy commercial tires of the type frequently described as giant pneumatics.

The well type rim is widely used on cycles and motor vehicles. It possesses the advantage of simplicity and lightness coupled with ease of removal and replacement.

The internal air pressure in the tube puts the cover into considerable tension. To render the rubber cover practically inextensible without seriously impairing its flexibility a cotton reinforcement is used. At one time the reinforcement consisted of a number of layers

running one way, known as the warp, crossing over and under the strands running the other way, and known as the weft. When subjected to tension the

BALLOON TIRES FOR NEW DIAMETER BEADED EDFE RIMS $720 \times 120$
$730 \times 130$
$.775 \times 145$
Considerable attention is given by tiro manufacturers to the design or pattern formed on the tread. Each manufacturer endeavours

## Inflation Pressures for Cord Tires

strands are continually le ent first one way and then the other. As a tire flexes when in use the strands work over one another and the friction and distortion creates a great deal of heat. This method of construction, although widely used until a few years ago, s now practically obsolete. The reinforcement used in all rubher tires to-day consists of four, six or more layers of cord made from fine Egyptian cotton. Each cord is completely embed led in rubber of the others, so that friction between them is eliminated and the tire if properly inflat-
long wear and a reasonablc degree of freedom from puncture the tread of the tire consists of a considerable thickness of rubber, while the outermost layer of cord is further protected by the breaker strip A, which consists of a strip of coarse canvas running right round. The tire is finally vulcanized or cured by raising it to a certain temperature so as to render it tough, completely elastic and reasonably hard. ed runs much
. I
 .  1

different sizes should be run, and all tires are to reach the cord reinforcement may ruin a tire liable to the same kind of failure if they are not run at the proper pressure. The pressure in any given size depends within limits upon the load carried. The table in page 1299 shows the pressures recommended by the Dunlop Company for the various permissible loads on various sizes. The diameter as a whole is not mentioned; only the width nced be considered. In many cars the load on the front tires is less than that on the rear tires, but the Dunlop Company recommend that, except in the case of high pressure tires, the front tires should be pumped as hard as the back in order to provide easy steering and to reduce wear of the tread.

The appearance of a tire is no guide to the inflation pressure. Long before a tire looks flat, irreparable damage may have been clone. The only satisfactory method is by the use of a pressure gauge applied to the valve independently of the punp. The gauge should be used at least once weekly and any shortage should be made up. If this is done regularly very little pumping is required.

## Results of Under Inflation

Reference will now be made to a few of the more probable results of under inflation. Every tire when working is flattened slightly at the part in contact with the ground and one result of this flattening is a slight bending of the side walls. If the inflation pressure is insulficient this bending becomes excessive and is greater than the natural flexibility of the walls can deal with, so that the cord frays and ultimately breaks. The effects may not be immediately apparent. l3y the time that the outer coating of rubber or the tire paint shows signs of a split running round or partly round the side wall, the cord reinforcement may be ruined beyond repair.

A further result of under inflation is excessive wear due to the tread not being sufficiently supported and therefore being flabby, so that it distorts and scrapes over the road much more than usual. This wear is additional to the normal wear due to the transmission of stcering stresses and the driving and braking efforts.

The front wheels on nearly all cars are splayed outwards slightly, so that there is a tendency to wear rather more on the outside than on the inside. When the tires are insufficiently inflated, the outer pait wears down rapidly. In the ordinary way any differences are small and can be equalized by turning the tire round about every two thousand miles.

Another form of trouble known as a concussion burst is due to a tire striking in sharp projection, such as a brick, at speed. Such a blow may be so violent and so localized that it will fracture one or two of the cord reinforcements, and this trouble may spread until the cover bulges or bursts. The effects may not become appaient until several weeks after the actual blow causing the trouble. The probability of damage is reduced to a minimum by running the tires at the proper pressures.

The front wheels of a car may lo parallel to one another but should preferably be given a small amount of " toe-in," the front edges of the rims being between $\frac{1}{8} \mathrm{in}$. and $\frac{5}{16} \mathrm{in}$. closer together than the rear cdges. Any departure from these conditions of alinement will result in excessive wear.

Apart from troubles due to under inllation or non-alinement, the amount of wear of tires depends very greatly upon the manner in which a vehicle is driven. The forces exerted botween the tire and the road when a car is accelerated or braked suddenly are very great and are all transmitted through the tires. It will thus be evident that the service obtainable from tires is largely within the control of the driver.

Care of Tires. However tough the rubber of the tread be, it is liable to be cut by sharp Hints, nails, glass, etc. A snall superficial cut is of no importance, but a cut sufficiently deep
to reach the cord reinforcement may ruin a tire
in a short time owing to moisture reaching the cotton and causing it to rot. The trouble may thus spread outwards from the original opening and ultiniately result in a burst which is too large to repair. A lookout should therefore be kept for deeper cuts, and they should be clcaned out and filled up with some epecial rubber com position.

Rubber is rendered soft and spongy by exposure to oil or paraffin. Any oil on the tires due, for example, to a leaky back axle or pools on the garage floor should be cleaned off with a rag and a little petrol. Petrol itself is a solvent of rubber, but evaporates so quickly that it cannot in the ordinary way causc any damage.

Whenever a puncture occurs, the first con sideration should be the cause of the trouble and the cover should therefore be examined carefully for evidence of a sharp flint. the point of a nail, ctc. Punctures or cuts in tubes may be repaired by vulcanizing or patching. The former metliod need only be applied when the cut is large, and is best left to tirms liaving suitable vul canizing apparatus. The possession of vulcanizing equipment by a private owner is
seldom worth while. Most punctures can, however, be repaired quite readily by patching, a.nd the
following reinarks will apply to most of the puncture repait outfits avail able to-day

The tube must first be thoroughly cleaned and

Fig. 8. Removing and replacing straight sided tires fittec to well type rims. When cover at $A$ is pushed down into the well, the edge at $B$ will come over the rim easily. Force must not be used rendered free of oil, grease, or moisture. This may be effected by a little petrol applied with a rag or by rubbing with the special perforated metal scraper supplied with the outlit. Solution from a tube is then applied over a sufficiently wide area and in some cases the surplus is scraped off at once with a knife; in other cases the patch must not be applied until the solution has become tacky, or almost dry.

While the solution is drying the patch can be cut out from the shect, the edge heing bevelled by a pair of scissors. An attempt may then be made to tear it in halves across the middle. The linen protecting the prepared side will thereby be torn in halves, but the rubber will yicld and will not be allected. Half of the linen may then be peeled off and care must be taken that the fingers do not touch the surface which is thus exposed. This exposed surface should then be applied to the tube, as shown in Fig. 7.
The other lialf of the linen should then be pulled off and the remainder of the patch stuck down. Finally the patch should be rolled hard or worked down with considerable force to ensure good contact with the tube. Neglect of this final operation may make it necessary to remove the patch-a somewhat difficult operation-and apply a fresh one.

Many small punctures cannot readily be found by inspection and it is then necessary to remove the tube completcly, inflate it with air as far as this can safely be clone, and immerse it in water. A small bowl of water, in the absence of a large receptacle, is sufficient for this purposc. Each section when immersed should be watched carefully for bubbles of air, which in the case of a small hole may only rise at intervals. The position of the puncture when found should be marked with pencil, but the whole of the tube should be tested for any fuither punctures. A slight leakage from a tire may be due to a defective valve. This may readily be ascertained by turning the wheel until the valve is on the top and then testing its tightness by means of a small cup filled with water. Should there be any leakage the inside of the valve must be replaced.

## Removing and Replacing Tires

Reference has already been inade to the ease with which a straight-sided tire can be removed from or replaced on a well type rim. The method of doing this is illustrated in Fig. 8 The edge should not in any circumstances be forced over the rim, as no useful purpose is served and it may be damaged. Before removing the tire all parts of the valve should be removed and both edges of the cover should be pushed right into the well at the part diametrically opposite the valve. The edges of the cover near the valve may then be gently levered over the rim. When replacing the cover one edge should be pushed over the llange of the rim right down into the well and the edge of the other side of the cover can then be pushed easily over the flange. The tube should be slightly inflated but not stretched tight and is then placed in the cover with the valve projecting through the hole in the rim. In many cases the valve projects towards one side and the tube must therefore be placed correctly in position. The second edge of the cover may then be placed in position by pushing it down into the well of the rim at a point diametrically opposite the valve, and it nay be gradually worked over the Hange. The last few inches may be forced on, if necessary, by small levers.

The removal and replacement of beaded edge tires presents somewhat greater difficulty, since the beads have to lie sprung over the elinches of the rim. To remove a tire the straight end of the lever is forced in as shown in Fig. 9 and the lever is bent round, using the clinch of the rim as a fulcrun, as shown in Fig. 10. Two or three levers will have to be emploved, working right round the rim in this manner.

In general it is sufficient merely to remove one edge of the tire, leaving the other on the rim. The tube should be partly inllated and then inserted into the cover and as far as possible over the rim, the valve being inserted

Figs. 9 and 10. Removing a beaded edge tire. Fig. 11. eplacing a cover. Fig. 12. The tube must not be nipped, as shown bere, when replacing cover
through the hole in the rim. Starting near the valve the edge of the cover may lic inserted in the clinch and worked into position gradually all the way round, using the hooked ends of the tire levers as shown in Fig. 11, hit care must be taken that the lever clocs not nip the lube, as shown in Fig. 12. Two or three levers should he used. but it will generally lue necessary to expend some effort to force the last section of bead over the clinch The levers should always be held firmly, otherwise the elasticity of the tire may cause them to jump "p violently into the face of the opelator or a bystander.

TISSUE : The Dress Fabric. All woven fabrics are tissues in one sense, and certain of them are officially described as woollen lissurs or worsted tissues in British trade returns. The F'rench call light cloths tissues as distinct from heavy cloths or draps. The word is often used in Euglish in order to denote tinsel cloths.

TOADFLAX. There are some charming annual and perennial plants among the toadflaxes, all suitable for the rock garclon and llower bo:cler. The most vigorous kind is the Dalmatian toadfan (Linaria dalmatica): it

Toadflax. Purple double-lipped flowars of Linaria
grows 3 feet high bears yellow flowers in summer, and thrives in ordinary soil. Linaria alpina is a pretty little plant for the rock garden, bearing orange and purple flowers. The Kerilworth ivy (Linaria cymbalaria) is a trailing wild plant useful for planting in walls ; it has lilac-coloured flowers. It is best to raise these plants from seeds sown in boxes in a frame in spring. The annual toadilaxes are easily raised from seeds sown out of doors in spring where the plants will bloom in summer: the chief species are bipartita and maroccana.

TOAD IN THE HOLE. The dish known as toad in the hole can be made from 2 lb . mutton or beef, $\frac{1}{2} \mathrm{lh}$. flour, 3 eggs, $1 \frac{1}{2}$ pints milk. Sieve the flour and salt into a loasin, stir in the eggs and a little of the nilk, and beat all to a smooth batter. Gradually work in the rest of the milk and let the whole stand for at least half an hour.

Free the meat from fat, skin, and hone, cut it into neat slices, , ry these in hot dripping, and then put them into a greased pie-clish. Sprinkle them with salt and pepper, pour the batter over, and bake the whole in a moderate
oven for $1 \frac{1}{3}$ hours. Serve it very hot, with a folded naplin pinned round the dish. If preferred, this can he marle witl sausage or cold meat, when it will require only about an hour's baking. See Batter; Sausage.

TOAD LILY. 'The chief species of toad lily is Tricyrtis hirta, a hardy, or ucarly hardy, herbaceous perennial, with white, hairy stems, alternate lance-shaped leaves, and white, violet-spoterl flowers in autumn ; height about $2 \frac{1}{2} \mathrm{ft}$. It should have a sheltered, sumny position in a friable loamy soil. Propagation is by division in spring. These plants may be grown in pots in the greenhouse.

TOADSTOOL. The popular name of toadstool is usually applied to an uneatable fungus as distinguished from eatable agarics, of which the common mushroom is an Axample. More than 1,000 species of agarics are known, some being poisonous.

It is often difficult to distinguish between edible and non-cdible kinds. Suspicion should be aroused if any fungus has a thin cap as compared with its gills, and if the latter are of even length; if its collar is wehbed or its juice milky; and if it quickly decays into a dark Huid. Caution should be used, also, if the stalk grows from one side of the cap.
The conmon edible mushroom grows naturally on hilly slopes or in open meadows, and in its carly stage is like a small white globe. This form is followed by development of a Hattish top with rough, brownish white skin and pink gills, the latter being just clear of the stem. When fully mature the gills change from pink to brown. and tinally to a colour that is nearly black, the skin easily peeling off, quite unlikic that of toadstools. It is best never to gather what are apparently mushrooms growing in woods, under trees, or other shaded places, unless with intimate knowledge of mycolog.y. Even in open places indiscriminate picking is risky. See Fungus: Mushroom.

TOAST. Brearl should be toasted evenly and only on the surface, and it must fecl quite crisp to the touch. It is served cither buttered or as dry toast.

Toast is used extensively for many culinary purposes. It forms a foundation for dishing various savouries, vegetables and small birds. Toast cut in shapes is used as a garnish.
1)ry toast should be macle with bread which is at least 24 hours old. Cut as many thin, even slices as will be required and toast each piece under the gas grill, or an electric toaster, or on the fork before a clear fire.

When the slice has been toasted each side lay it on a board, press it flat, and at once remove the crust, then stand it upright where it can be kept warm while the remaining pieces are locing toasted. Toast should always be made as required; if kept waiting it will be hard and leathery. If the crust is not cut off immediately, the steam cannot escape and the toast becomes sodden

For buttered toast, the bread should be cut rather thicker. After being toasted and the crust removed, the slice should lie laid on $\Omega$ hot plate and the butter placed on it in small pieces, and as the butter melts it should be spread over lightly without scraping the toast underneath. Lay the second round, after toasting it, on the first, and butter it as in the first instance. Cut the slices of buttered toast into neat pieces and pile them on a very hot dish, covering them over.

For cinnamon toast mix equal parts powdered cinnamon and castor sugar, sprinkle thickly on the toast after buttering and place under hot grill or before a clear fire until the sugar melts and the cinnamon is incorporated with the butter

French toast is a good way of using up slices of bread and butter which have been left over from tea. It should be made with rather thin bread and butter. Two slices are laid one over
the other, with the butter side inwards. They are lightly pressed together, and should be toasted in the ordinary way. No extra butter is necded, as the butter already on the bread penetrates the soft part and also imparts a rich, crisp taste to the toast. It should be eaten very hot straight from the fire. Set a plate on the hearth to catch any falling grease.

## Toast Water. This is a refreshing and

 wholesome drink. To make it, a verv thin slice of bread sbould be toasted until it is thoroughly brown and dry all over, but it must not be burnt or blachened in any way. Put the slice of toast into an carthenware jug and nour over it $1 \frac{1}{2}$ pints of boiling water, then cover over the jug and set it aside till cold. The success of toast water greatly depends on whether the water is actually boiling when poured on to the toast and whether it is freshly made.Toasting Fork. When toasting bread or cakes in front of an open coal or gas fire the use of a special fork is advisable. The simplest form consists of three or four short wire prongs and a long handle of wood or metal. Mere ornamental designs are also employed and reproductions of old designs in brass can be purchased for a few shillings.

Toast Rack. Toast racks are made of chima, carthenware, silver, Shefficld plate, and electro-plate. There is not a great varicty of styles in these pieces, but metal designs copied from lith century models are usually more elegant than later ones. Specimens of the 18 th centurv toast racks are fairly often seen. Some of them are boat-shaped, with beaded borders. simall china and semi-porcelain toast racki are made to match most modern tea and dinner services.

TOBACCO. In purchasing his tobacco the pipe smoker has to consider the qualities which the desires in his particular brand, and also the strength which suits him. The latter considcration is the more important of the two, and the proof of it lies in the fact that practically every good pipe tobacco can be olstained in the three standard strengths, mild, medium, and full flavoured.
1.ipe tobaccos are sold cither loose or in packets of 1 oz . and 2 oz . Larger quantitics are retailed in tins containing $\frac{1}{4} \mathrm{lb} ., \frac{1}{2} \mathrm{lb} .$, or 1 lb . While the majority of smokers usually buy their tobacco in small quantities, it is of ten convenient and slightly more economical to lay in a week's supply or more at a time,
Tastes differ proverbially as to the choice of a brand. It does not necessarily always follow that the more expensive sorts are the best for everyone. A good mixture at 10d. or ls. per oz. may be quite as satisfactory as one costing ls. 3d. per oz., although it lacks certain choice ingredients only to be found in the latter. It is all a matter of individual taste.
The first object is to get a cool-smoking tobacco. However fragrant and agrecable to the palate a mixture may be, the pleasure of smoking it is entircly spoilt if it is too hot on the tongue and perhaps has a tendency to heat up the howl of the pipe. It is the lighter mixtures that are apt to offend in this way unless the hlending is skilfully arranged ; those which are liberally sprinkled with dark shreds burn more slowly and with a steady glow. For those who can smoke the strongest. tobaccos no dilficulty is likely to arise, and when the pipe is once properly lit a long, cool, and fragrant smoke should result.

The choice of a mixture is assisted by some knowledge of its composition. The principal ingredient is ncarly always the Virginia lraf in one or other of its numerous forms. Of all kinds of tohaceo this is casily the most popular. Virginia is graded in so many different qualities that only an expert can distinguish them all, but the smoker has usually no difliculty in picking one out for himself to be sampled at
home. Severa! may be tried before the right mixture is obtained.
Between the two extremes of light aud dark is the widely popular medium, which is neither too hot nor too strong, and generally has all the fragrant qualities, with only a inoderate amount of the dark leaf. Even this, however, is too strong for some smokers, who should therefore select a light quality, as, for instance, one in which a quantity of orienta! leaf has been blended with the Virginia. In most of these the leaf is cut very fine, just as it is in such strong, full-lla roured tolnaccos as shag and returns. In other mixtures a broad-cut leaf is used, and in some a double-broad cut, so that even in the matter of cut the smoker has a variety to selcet from.
The range of tobaccos is further extended by the cut plugs, which are extensively in use. This is a very handy form of tobacco for pipe smokers. The p!ug is cut up into thin slices. which are packed in 1 oz or 2 oz packets or in 4 oz tills From 2 to 3 slices are sufficient to fill the bow! of a pipe of average size. They should be rolled in the hand before being loaded into the pipe bow!. Some smoliers prefer to buy their tobacco in plug form and cut it up for themselves. Cake tobacco is a nother form which is wide! y used like the plug tobaccos, it is sold in various steengths, the milder qualities being light in colour and the strong tobacco almost black.

It is in the loose mixtures that the retailer turns to account his knowledge of all the various kinds of tohacco leaf, the subtle variations in strength and llavour which different soils produce in the plant, and his skill in blending, for which long experience is required. One obvious advantage in buying the loose tohaco is that the smoker can see what sort of mixture he is getting, although, as a matter of fact, the average snoker knows comparatively little of the echnical side of the subject. and is generally guided by considerations of price It is therefore advisable in purchasing toracco as with most other things, 10 deal with a firm of repute

Blending Tobaccos. Tobaccos of several strengths are used, varying in colour from a pale golden yellow to dark brown and black. These are laill out on a specially made table to be dried and matured, and are then blended in the proportions required in accordance with particular recipes. The bulk of the tobacco is American, the produce of Virginia, Kentucky and the Carolinas, but fine Turkish is also employed. Some of the more expensive blends receive a sprinkling of latakia, the aromatic leaf of Syria, which imparts a distinctive Havour that is highly esteemed by some smokers.

Recipes for bending have a commercia! value, and the details of many of those in the possession of manufacturing firms are carefully guarded secrets. Some retailers follow certain old-established reciess which they obtained from their predecessors in business, and these form an asset of distinct value where a particular mixture has been popular perhaps for many years with a large circle of customers. Dealers who have expert knowledge make blends of their own, and sell them not only loose, but also in packets, where they have proved particularly successful, often with their own registered trade marks. Small dealers who are not themselves expert in this c'ass of work may produce blends from recipes supplied by the large manufacturers.
Tobacco Pouch. Most pipe smokers carry their tobacco in a pouch or case made in various si\%es and of some soft material such as india-rubber or oilskin, or a variety of leather, such as buckskin, with an inner lining of india-rublier Tobacco is also kept in leather cases without india-rubber. A widely popular style of pouch is made entirely of rubber, one half folding over the other in which the tobacco
is contained. It is best to choose one in which the material is moderately thick, as the rubber is apt to wear and to cut at the creases.

Pouches of buck. skin or otbcr material with a lining or pocket of rubber are more substantial in appearance, and with ordinary carc will last for ycars. Reindecr, antelope. chamois, doc, calf, and other skins are employed and a silver shield or embroidered mono. gram is a customary form of ornament. The leather wallet is another favourite variety, made from pigskin, crocodile, scalskin, and other
 eathers, strongly sewn together. Oilskin pouches are rect- some decorative value because of its fine leares. angular in shape and can be obtained in both For experiments in tobacco growing the large and small si\%es. See Pipe; Smoking.
TOBACCOPLANT. The favourite tobacco plant for gardens in Great Britain is the half hardy annual Nicotiana affinis, which bears white llowers which are delightfully

## TOBOGGAN FOR WINTER SPORTS

## How to Build a Clipper for Two Adults

The amateur who wishes to make a tobozgan should consult also the various articles in our work that deal with the tools and materials used by the woodworker, such as Amateur Carpentry; Bit;

As the sport of tobogganing consists mainly in coasting very rapidly downhill, the design of a toboggan, which is a form of sledge, must be strong enough to withstand rough usage. In its simplest form the tologgan consists of boarding fixed across a couple of wooden runners, but more claborate forms are in use to accommodate parties instead of a single person.

A clipper toboggan large enough to carry two adults is shown in Fig. ], its component parts being detailed in Fig. 2. Only wellseasoned pine, ash, or elm of the best quality sliould be used, cut to size and ready planed. The timber and other materials required are shown in the table.

Having made sure that each piece of timber is cut exactly to size and properly squared, the rods for the hand grips B are prepared. The centre of one of the long sides of each rod is found and a parallel line drawn through the point from end to end of the rod : then four ${ }^{3}$ Io $i 11$. diameter holes are bored through each rod from points marked off on the centre line. The first point is $1 \frac{1}{2} \mathrm{in}$. from the right end; the second, 7 in . from the $\mathrm{l} \frac{1}{3}$ in. point; the third, 7 in . from the 7 in . point ; the fourth 7 in . from the last 7 in . point. All the points must be placed exactly on the centre lines, then the holes are carefully bored through and afterwards countersunk with a rose-bit.

Both erlges of the side of the rod from which the holes were countersunk are now planed to a slight hevel, as shown in Fig. 3, then both ends of each rod are rounded as detailed in the same diagram.

The two runners $C$ are the same sioc and shape, the marking out of the planks from

|  | Long <br> ft. <br> inf | Broadl <br> in | Thick |
| :--- | :---: | :---: | :---: |
| in. |  |  |  |

which they are made heing as follows: A space of 8 in. is marked off from the right ends, then a line at rigl:t angles is drawn through each point across the breadth of each plank. A space of 4 in ., measured from the upper left corner, is marked ofl on the annual $N$. tabacum may be sown in gentle heat in early spring and planted out in a sunny border in June. The plants should be freely watered, and will be ready for gathering for drying at the end of Scptember.
scented in the evening. It is mised by sowing seeds in a heated glasshouse in February and planting the seedlings out of doors in May or carly Junc. There are several coloured varieties of red, crịnson or pink llowers, but they are less fragrant than the white ones. All makc good pot plants for the conservatory. Nico. tiana sy!vestris is a handsome plant. 5 ft . high, with large leaves and white tlowers in summer. It is raised from secd sown under glass in spring. Commercial tobacco is olitained from Nicotiana tabacum a filant which is oi

parallel line draint through the point from end iron. Eive $\frac{3}{18} \mathrm{in}$. dianeter holes arc drilled from $\Omega 3 \mathrm{ft}$. 10 in . length of 1 in . broad $\frac{1}{2}$.round to end of the hoard; the runncr-planks and through the centre of the thickness of each strip iron. Eight $\frac{3}{16}$ in. diameter holes are loard are then placed flat on the bench in the length from the points detailed in Fig 7 the positions shown in lig. 4, the centre line on the hoard being a continuation of the line previously drawn through the 8 in . point on each runner. A space of $9 \frac{13}{10} \mathrm{in}$., mensured end to end of each length, then the points from the lower side of the lower plank (i.e. for the holes are marked off. The first point the plank nearest the front of the bench), is marked off on the line on the board, then a similar space is marked off from the upper side of the upper plank.
The next step is to draw the curves with a compass set to a radius of $9 \frac{18}{18} \mathrm{in}$., using the points marked on the lines as centres, as rletailed in Fig. 4. If a large compass is not available, the curves may be drawn by machi
arranging a pencil, tacls, and loop of string as from

shown. A space of $\frac{7}{8}$ in., measured from the upper side, is marked off on the surface of each plank, then a parallel line is drawn through each point fiom end to end of the plank, as detailed in Fig. 5.

Four' $\frac{3}{16}$ in. diameter holes are bored through the thickness of each plank from points marked off on the parallel lines. The first point is 3 in . from the right end of each plank; the second, 6 in. from the 3 in. point; the third, 11 in . from the $f(\mathrm{in}$. point ; the fourth, 11 in . from the 11 in point, Fig. 5. The planks are now cat to shape, the waste wood being removed from the right ends by sawing along each curved line with a keve hole saw, then the curves are neatly finished with a spokeshave. The left end of each plank is cut to the angle shown in Fig. 5, by sawing along the diagonal line.

The three pieces of wood for the crossbars $D$ are prepared by planing two of the long cdges of one of the broad surfaces of each piece. The portion to be removed from each edge is marked off as follows: From the right and left long edges mark off a space of $\frac{\mathrm{in}}{} \mathrm{in}$. on the surface and right and left sides, then draw a parallel line through each point from end to end of each piece of wood (Fig. 6). The three brace irons $E$ are each made from a 15 in . length of $\frac{3}{} \mathrm{in}$. broad, $\frac{1}{2}$-round strip

second, 1$\}$ in. from the $\frac{5}{8} \mathrm{in}$. point ; the third, $5 \frac{1}{4} \mathrm{in}$. from the $1 \frac{3}{4} \mathrm{in}$. point; the fourth, $5 \frac{1}{4} \mathrm{in}$.
from the 54 in. from the 51 in ; the fifth, $1_{4}^{3} \mathrm{in}$. from the last in. point.
The points are marked with a centre punch and the holes bored with a $\frac{3}{16}$ in. twist drill fitted in cither a brace or a hand-drilling length from the points detailed in Fig. 7, the drilled through the centre of the thicliness of points being placed on centre lines. The centre cach length from the points detailed in Fig. 9. of the brealth of each $\frac{1}{2}$-round side is found, A centre line is first drawn, then the points are and a parallel line drawn through the point from spaced in the following order: The first point on each length is $\frac{1}{2}$ in. from the right end; the second, $1 \frac{1}{2}$ in. from the $\frac{1}{2}$ in. point ; the third, $9 \frac{1}{4} \mathrm{in}$. from the $1 \frac{1}{2} \mathrm{in}$. point; the fourth, 6 in from the 94 in point ; the fifth, 131 in. from the 6 in. point ; the sixth, 6 in. from the $13 \frac{1}{8}$ in. point; the seventh, $5 \frac{1}{8} \mathrm{in}$. from the $(8 \mathrm{in}$, point ; the eighth, 4 in . from the $5 \frac{1}{8} \mathrm{in}$. point. The holes are drilled and countersunk in the same way as those bored in the brace irons.
The ends of each length are next marked and hent to the angles detailed in Fig. 10. A space of 3 in., measured from the right end, and a space of $5^{5}$ in. measured from the left end, are marked off on the $\frac{1}{2}$-round side and slightly incised with a cold chisel. The left ends of the lengths are lieated to a bright

Fig. 6
red for about 6 in . and bent from the incised marks to the angle of the left end of the runners, as shown in Fig. 10. The right ends are similarly treated, aft.is which each length is reheated and bent $t o$ the shape of the curved ends of the runners.

Useful hints for manipulating ironwork will le found in the article on Forge. If the home worker has not the facilities for this part of the work the blacksmith from whom the strip iron is bought would doubtless do the bending and drilling for a reasonable charge.
To assemble the parts the runners are placed on a level surface and set in position 12 in . apart, exactly parallel to each other and in line, and hot glue is applied to their upper sides. The seat boards are fitted in position on the runners, as detailed in Fig. 11, both ends of each board being secured by three $\check{\sim}$ in. oval wire nails. Hot glue should be applied to the long sides of the boards before fitting them in place. The hand grips $B$ are glued and nailed to the sides of the seat, then a 2 in. screw is inscrted into each of the countersunk holes in the hand grip and driven firmly into the seat boards.
The crossbars D are glued and fastened by 3 nails each to the underside of the seat, the position of each bar being detailed in Fig. 2. A 2 in. screw is driven into both ends of each bar from the holes previously bored through the runners, countersinking the holes before inserting the screws. In order to secure the bars further, a $\frac{3}{16} \mathrm{in}$. diameter hole is bored through the seat at each of the points detailed in Fig. 11, then each hole is countersunk and a 2 in . screw driven into the centre of the crossbar below. It may be noted that the screws will be easier to drive if a small gimlet hole is made for each and a little vaseline applied to the flireads.

Fitting Brace and Runner Irons
The brace irons E are fitted to the crossbars as shown in Fig 2, each iron being secured with three 1 in . screws. A $\frac{3}{16} \mathrm{in}$. diameter hole is bored with a gimlet through each runner from each of the holes in the angles of the brace irons, then a recess of the exact size of the nuts on the $1 \frac{1}{4} \mathrm{in}$. bolts is cut at each hole on the outside of the runners and a nut placed in it. The bolts are inserted into the holes in the angles of the brace irons and driven in with a screwdriver until they are firmly screwed into the nuts, as shown in the sectional diagram in Fig. 12 . If the ends of the bolts project, they should be filed down nearly flush and then riveted.
The runner irons $F$ are now fitted in position on the runners and attached with screws. A $1 \frac{1}{2} \mathrm{in}$. screw is driven into each end hole, and a 1 in. screw into each of the other holes. The drawrope $G$ is attached by first enlarging with a $\frac{3}{8} \mathrm{in}$. drill, the $\frac{1}{8} \mathrm{in}$. diameter hole previously bored at the curved end of each runner, then an end of the $2 \frac{1}{2} \mathrm{yd}$. length of rope is inserted into each hole from the inner side of the runner and secured.

The woodwork should be well smoothed with sandpaper, and all the corncrs and edges carefully rounded with a rasp. A nail punch should be used to drive each nail in the seat, hand grips, etc., a little below the surface of the wood, to remove a possible cause of torn clothes or injuries while sledging. When the runner irons have been polished smooth and bright with coarse emery cloth, the toboggan is complete and may be given several coats of good varnish paint as a finish.
TOBY JUG. The original Toby jug used for holding beer was in the form of a stout figure of a man wearing a cocked hat and knecbreeches, and generally embodying a variety of glazed colourings. A typical example shows a squat little figure attired in a purple coat, green waistcoat, yellow brecches, and white stockings, in Staffordshire pottery. Potters
frequently rang the changes on these colours by varying the colour of the coat or breeches in products of the same inould. There are many variations in the design of the figures, which have recognized values among collectors according to their artistic merit and rarity.
Favourite designs include the typical English squire, John Bull, the sailor, the snuff-taker, Simple Simon, the postboy astride of a barrel, the watchman with his lanthorn. Others represent historical characters like those which bear the name of Nelson, Napoleon, Jord Howe, and many other celebrities in the later varietics of the Toby jug. Green and buff glaze is common, but at least one variety is blue and white with a flat beaver hat.

Modern Toby jugs of brown Doulton and other ware are decorated with small facsimiles of the old English figures and other designs in white enamel.

Toby Jug modelled by Walton early 19th century
British Museum
tumbler one-quarter full of boiling water. Cover it over until the sugar is dissolved, and then add a wineglassful of whisky.

According to the old practice toddy or grog should be made in the large, wide-mouthed glasses generally known as ruminers. The whisky is always added last, and according to one of the old recipes it should be laid in spoonfuls on the top of the boiling water. This process is sup. posed to get rid of fuscl oil.
In serving toddy it was customary to use ordinary wineglasses as well as the rummers. These were intended for the ladies of the party, and were filled from the rummer with the. long, curved silver spoons or ladles known as toldy spoons.

Many choice examples of cut-glass toddy tumblers and spoons are to be found in private houses, and are still brought into use on occasions when it was These may be formerly the custom to brew a bowl of punch. bought singly or in sets of three in different See Rummer. sizes. Toby ware is also used for tobacco jars and for small cructs.
TODDY. Toddy is a mixture of whisky, . Toddy is a mixture of whisky, should be grown in a closed case kept moist sugar, and hot water. To make it, put into and shaded. One of the most beautiful is a tumbler a lump of sugar, a piece of thin Todea superba. See Fern. lemon peel, and a silver teaspoon. Fill the Toe. See Foot.

## Toffee and Toffee Sweetmeats

## Recipes for Butterscotch, Caramels, Humbugs, and Other Varieties.

This contribution deals with confections that require a basis containing as its main ingredients sugar and butter, or cream. Other sweet-making information is given under the headings Chocolate Makirg; Nourat: Sweets: Turkish Delight. See also Glucsse Sugar: Treacle; and the entries on other ingredients

The hard sweetmeat known as toffee is made chiefly from butter and sugar. Unlike other hard sweets, such as rocks, for which white sugar is userd, a large proportion of brown sugar or treacle is used in most toffee-making to prevent granulation during boiling and stirring, and a fatty constituent is required Glucose or cream of tarter is also included in many of the recipes. Various flavourings or nuts are added to make the different kinds. Recipes for the toffees are here given before proceeding to the toffee sweetmeats.
A good plain toffee, often known as hardbake, can be made by melting 3 oz . butter in a small bright pan, stirring in 1 lh . brown sugar and continuing to stir until the mixture bernmes hard and brittle when a small portion is tested in cold water. If stirring is discontinued the toffee will burn. When ready pour it into an oiled tin and leave to set. Before it is quite hard mark it into squares.

Butterscotch. This is a delicious variety of toffee distinguished by being made with white sugar instead of brown. Place 1 lb . loaf or granulated sugar into a saucepan con

Toffee. Fig. 1. Butterscotch, made with white sugar
taining 1 gill fresh milk. Heat slowly and stir occasionally till the sugar has melted. Arld a pinch of cream of tartar, and 3 oz. fresh butter, the latter a small piece at a time. Boil the mixture until it is a light coffec colour, drop a little of it into very cold water, and leave it a few seconds.

Take out the little lump, and, if it is quite brittle, add a few drops of essence of lemon and lemon-juice, and pour the mixture at once on to oiled tins or plates to the depth of a $\frac{1}{4} \mathrm{in}$. When it is nearly cold, cut it into oblong-shaped pieces, as shown in Fig. 1. If to be stored in a tin first wrap each piece in wax paper, and then in tin foil. Keep the toffee in a cool, dry place.

Everton Toffee. The ingredients for Ever ton toffce are 2 lb . white sugar, $\frac{1}{4} \mathrm{lb}$. dark sugar (Barbados), $\frac{1}{4} \mathrm{lb}$. glucose, $\frac{1}{4} \mathrm{lb}$. fresh butter, $\frac{1}{2}$ pint milk, a pinch of salt, and a few drops oil of lemon. Melt the sugar, glucose and milk in a large pan, then place it over a slow fire, add the butter and boil to $270^{\circ}$. Stit in salt and oil of lemon very gently, and pour the toffee into greased tins. Brush these over with pure vaseline first. This is taste less and harmless, and, unlike butter and vegetable oils, frec from rancidity.
Ginger Toffee. To make ginger toffee, mix in a saucepan 3 lb . brown cane sugar and ${ }^{\text {g }}$ level teaspoonfuls ground ginger, and add about $\frac{1}{2}$ pint white vinegar and a lump of butter slightly larger than a hen's egg. Let these stand by the side of the fire until the sugar has melted, then boil them up and continue boiling until the toffee snaps when a little of it is dropped into cold water. Pour the toffee into oiled tins, and let it harden

Honey Toffee. Melt 1 lb . Ioaf sugar in $\frac{1}{4}$ pint water over the fire When it is on the point of boiling add 1 dessertspoonful glucose, $\frac{1}{4} \mathrm{lb}$. each honey and butter. and 2 or 3 table. spoonfuls cream Boil the whole to $285^{\circ} \mathrm{F}$., stirring all the time ; then pour it on to a buttered marble slab, and when cold break it up, wrap the lumpa in waxed papers twisted slightly at either end, and store in a tin

Nut Toffees. Walnut toffee is composed ol 1 lb . white sugar, 1 lb . brown sugar, $\frac{\mathrm{lb}}{}$ glucose. 2 oz. butter, a full ? nint water. \& lb

Toffee. Fig. 2. Walnut toilce cut into bars
walnuts, slightly roasted, a few drops oil of lemon. Boil to $270^{\circ}$ as already explained Remove the pan from the fire and add the walnuts, cither whole or chopped Stirgently PJace on the lire again for a few minutes, add the lemon and pour. Mark toffee deeply with oiled knife, and when set cut into hars
Almond and brazil nut or peanut toffice may be made in the same way, using blanched, skinued and neatly cut almonds or the other nuts in place of walnuts Coconut toffee is made a little differently. Put loz. butter in a saucepan, add to it when it is melted I small tablespoonful golden syrup and the same of milk. When these are mixed, add $1 \frac{1}{2} \mathrm{lb}$. fine white sugar and 2 tablespoonfuls desiccated coconut. Stir frequently and boil the mixture fast, until it candies and grains well on the sides of the pan. Stir in half a teaspoonful of vanilla and pour it out into an oiled tin. Leave it until cold and cutit up.
Peppermint Toffee. Put into a saucepan a tin of sweetened condensed milk, $1 \frac{1}{2} \mathrm{lb}$. brown sugar, $\frac{1}{4} \mathrm{lb}$. butter, and two tablespoonfuls golden syrup, and stir them at the side of the fire until they melt. Then place the pan directly over the lire and boil its contents rapidly, stirring all the time. When they are a dark chocolate colour, take the mixture from the tire and drop a little of it into a basin of cold water. If it hardens, the toffee is cooked. and some peppermint essence may then be stirred in. Pour all on to a greased tin and let it cool a little before marking it into squares, then set it aside to become quite cold

Russian Toffee. This is made with the following ingredients: 1 lb. brown sugar, I lb. white sugar, $\frac{1}{2} \mathrm{lb}$. glucose, $\frac{1}{2}$ pint milk, $\frac{1}{2}$ pint cream, $\frac{1}{2}$ lb. fresh butter, a few drops of vanilla essence. Place the sugar, glucose, and milk in a large-sized pan and boil carefully to $\because 60^{\circ}$. Add the cream, and bring up to $260^{\circ}$ once more. Add melted butter and boil to $270^{\circ}$. Remove from the fire, gently stir in the essence. pour into oiled tins, mark off when partly set. When cold, cut into squares as seen in Fig. 3. If desired to store, wrap the block in waxed paper and cut off the marked squares as required.

Treacle Toffee. The main ingredients of treacle toffee are 2 lb each of black treacle and brown cane sugar. Put these into a pan with a lump of butter about twice the size of a hen's egg, and lat them melt slowly at the side of the fire. Then boil up the toffee, stirring it all the time. and continue stirring until it hecomes brittle when a spoonful is dropped into cold water. Add a little vanilla flavouring, and pour the whole into an oiled tin.

Caramels. A softer type of toffee is the basis of the sweets known as caramels. Coffee, chocolate and vanilla are popular flavours.

Vanilla carannels may be either of the hard or soft varieties. For the hard caramels take $2 \frac{1}{2} \mathrm{lb}$. White sugar, 6 oz glucose, 1 pint cream, $\frac{16}{2} \mathrm{lb}$ tin condensed milk (unsweetened), $\frac{1}{2}$ pint milk, vanilla essence Place the sugar, glucose, and milk in a large pan. melt, and boil to $250^{\circ}$ Carofully add cream and boil continuous!y to $280^{\circ}$ Stir all the time. At $280^{\circ}$ rently stir in the vanillia, and pour into an oiled tin (olive oil) to the deptb of about $\frac{1}{2}$ in Mark deeply with an oiled knife into $l^{2}$ in squares before the mixture is set. When cold cut it right through and twist up the squares in waxed papers Chocolate caramels are similarly made by stirring in about $\frac{1}{4} \mathrm{lb}$ plain melted chocolate

For soft vanilla caramels take 2 lb . white sugar. $\frac{3}{4} \mathrm{lb}$. Barbados sugar, 3 lb . glucose, 1 quart cream. 2 oz. coco-butter, 1 pint water vanilla essence. Melt as before and add cream gradually at $250^{\circ}$. Slowly boil to $255^{\circ}$, stirring continuously. Just before removing the pan from the fire, stir in the essence. Pour on the oiled tin, mark off, and wrap up when cold

To make coffee caramels. melt l lb loa sugar and 6 oz . glucose in a pan containing a small teacupful of water, placing the pan at the side of the stove or over a very low lire so that the process may be slow. When the whole is reduced to liquid, boil it to $245^{\circ} \mathrm{F}$. then add 3 oz . butter and enough coffee essence to give the desired flavour. Continue boiling without stirring the mixture, and when it has reached $245^{\circ}-250^{\circ}$, pour it into a well-oiled tin, cutting it into squares when almost cold, with an oiled knife or a caramel cutter

Fudge. This type of toffee sweetmeat is of American origin and instructions for making two kinds are given in page 499. Vanilla chocolate fudge requires the following in gredients: $\frac{1}{3} \mathrm{lb}$. granulated sugar, 4 table spoonfuls cocoa powder 2 tablespoonfuls butter. 1 dessertspoonful golden syrup, small tin unsweetened condensed milk, about $\frac{1}{2}$ teaspoonful vanilla essence.

Blend the cocoa with the condensed milk to a smooth paste and add gradually to the melted butter in a small bright saucepan Add the sugar and syrup and stir while the mixture boils up Allow it to boil until a little dropped into cold water hardens to the desired consistency Add the vanilla essence to the

Fig. 3. Russian toffee, a very rich variety
mass, beat it up well and then put it into a nougat frame lined with waxerl paper to set.

Another recipe requires 1 teacupful brown sugar, 1 dessertspoonful golden syrup, teacupful finely grated chocolate, I teacupful milk (half milk and half cream is used for a richer fudge), 1 dessertspoonful glycerin, $\frac{1}{2}$ teaspoonful vanilla essence, and 1 oz . butter.

Place the sugar, butter, milk and syrup in a saucepan and bring to boiling point. Add the glycerin and hoil rapidly for 10 minutes, and stir in the chocolate. Continue boiling and test in cold water. Turn into an oiled tin and mark into squares when almost set.

Humbugs. These old-fashioned sweet meats are also called bull's eyes, and are made from pulled torfee cut into tho shape known as a cushion. (See the directions for cutting boiled sweets in this manner given in page 1244.) To make, dissolve $\frac{3}{4} \mathrm{lb}$. best brown
sugar and $\frac{3}{3} \mathrm{lb}$. loaf sugar with not quite $\frac{1}{2}$ pint water in a strong pan; the pan must not be tinned inside. When the sugar is melted add 2 tableoponnfuls glucose and boil to the soft ball, then by degrees put in $1 \underset{2}{1}$ oz. butter cut in thin slices
Boil again till the toffee will snap This can be tested by dropping a little of the syrup into cold water and breaking it between the thumbs : it should harden at once and break with a crack Pour the toffee mixture, with the exception of about two tablespoonfuls, on to an oiled marble slab. Then drop in essence of peppermint to taste. It is impossible to give exact quantities of essence required, as the strength varies in all essences
Turn in the edges of the toffee as soon as it can be handled and pull it until it is a light cream colour It may be pulled with the hands or thrown repeatedly over a candy hook, as explained in the directions for making rock in the article on Sweets. The toffee will take about 10 min to pull. The remaining toffee should be kept liquid in the pan over hot water

When the pulled toffee is ready turn the clear liquid on to an oiled dish. Take up small pieces and stretch them in thin strips: lay them along the pulled sweet, which should be in even lengths; straighten the length out and cut into cushions with a strong pair of scissors. The humbugs should be cream with pale brown transparent stripes.

TOFFEE PUDDING. To make this, take 10 oz . self-raising Hour, 3 oz . butter, 2 oz . granulated sugar, and $1 \frac{1}{3}$ oz. eac:! of shredded suet and laril. Make a short crust with the four, suet, and lard, and a little water, and roll it out to $\frac{1}{2} \mathrm{in}$. thick. Next cream the sugar and butter together and spread the misture on the pastry, which should then be rolled up and both ends securely fastened. Put it into a pie-dish and bake it in a quick oven for 35 min . As the butter and sugar ooze out of the pastry usc them to baste the roll, on whicls they will form a toffee-like surface.

TOILET. Cleanliness and nentnees are the chief factors of success in the evcryday toilet which achieves a well-groomed appearance. Well-brushed and cared-for clothes, clean linen and footwear, immaculate hands and hair, are most important. The morning loilet for those who go to busincess away from lome should be particularly efficient.

After a few exercises, and thorongh brushing of the hair, a warm bath concluiled by a colit shower, or sponge down, and followed by a lirisk rubbing with a loofah or hath brush and drying with a rough towel, has an invigorating effect on most people. A good rubbiug with the towel across the back of the neck and behind the ears stimulates the circulation.

When housewo:k nas to be done at honic. most women complete the toilet afterwards A cap should be worn to proteet the hair from dust while sweeping, and the hands should be protected by rubber or wash-leather gloves when porsible.

Articles for the toilet such as hair brushes, tooth brushes, sponges, soaps, powders, creams and lotions, should be of the best quality. It is a mistake to economiz on these things. In paricular powders and soaps for the baby: toilet should be absolutely pure. Should a wrong soap have been used--that is, one in which there is free alkali, and irritation of the skin has been caused, gently ruh in a little pure olive oil. The powder must contain no white lead and the pulf must be kept scrupu lously clean. See Baby, Beauty Culture; Hair, Shaving: Soap: etc.

Toilet Cover. See Duchesse Cover.
TOILET MIRROR. Of the toilet mirror as a distinct article of furniture there are many varieties. Some are fitted into a frame and
swing between pair of supporting columns with a cross-piece bet ween, or perhaus with a hase in which is a drawer. Others have a flap that lets down in front and rests upon supports that pull out. The fraine may be of mahogany, walnut, or the cheaper woods. Sonic are inlaid with a line of satinwood, while others are hand painted or lacquered in black, green, red, or yellow, with raised designs gilded and lined with black in the Chinese style. Triple mirrors are also made both framed and frameless. (See pages 390, 391.)
Toilet mirmes can be placed on any table or chest of drawers, provi. ded it is a suitable height. For a ma hogany piece a plain Chippendale design is perhaps more suitable. Mirrors with only a frame, or only $n$ frame with $n$ box or shelf at the base, are frequently very useful for hanging on the walls of bedrooms, bathrooms and dressing-rooms. Sometimes these are hung above a dressing-table. Others are fixed to a door or the inside of a wardrobe door.
Many of the mirrors made to-day are reproluctions of l8th-century picces, and a typical example is here illustrated of Qucen Anne style in walnut with gilt gesso dicoration. Most of these mirrors swing from uprights that rise from bases baving three trinket drawers, this being a pattern that has heen much copied Their frames have a decorative shaping at the upper part, and occasionally a cresting such as is seen on the wall mirrors of the prriod. Some of these are inlaid with veneers, and occasionally two or even three sets of drawers, one above the other, are seen in the lower part.

A magnificent example of Qucen Anne worl: in the Victoria and Albert Museum. It is of pinewood and is decorated with gold lacquer in the Chinese style on a green ground. Jelow the glass, which is in a rectangular frame are small drawers and pigeon holes very like those seen in a bureau, the resemblance being carried further by the presence of a lid that when open serves also as a desk.

Later, in mid-Georgian days many ova! toilet mirrors were made. The cxample here illustrated with the cut-glass toilet set is typical of the mahogany style in vogue with its curved support and lower part inlaid with satinwood lines, bow fronted, and having three drawers. See Bathroom; Dressing Table. Mirror: Qucen Anne Sty!e ; Silvering.

TOILET SERVICE. Sets of toilet ware for the washstand are sold under the name of toilet services. They are sold in single or double sety. The single set of five pieces is composed of basin and ewer, chamber, soap dish, and tooth-brush vase. The double service is composed of 12 pieces, which includes a toilet pai! and sponge bowl. The last two articles can be bought separatcly and added to the single service. Sets in stock patterns

Toilet Mirror in Queen Anne style, made of walnut and decorated with gesso work
are to be had in many good designs, any article of which can be replaced in cvent of breakage. Spode designs look particularly well with manogany, and are reproduced with squat-shaped or tall ewers.
Servises in plain bright colours mitist be chosen with due regard to the colour scheme of the room. Sometimes the tiles in the fireplace arc matched, or a predominating shade in carpet or curtains. For small and corner washstands the mininture services in a Spode design or in willow pattern are pretty. For a country cottage leadless glaze toilet services are liked, also sets of rough brown pottery with vellow glaze inside. Glass services are heautiful and costly, whether of cut crystal or decorated with gold.
TOILET SET. A toilet set usually refers to the collcction of articles that stand on the dressing-table, and the toilet service to those that stand on the washstand, although the two are sometimes confused. The usual constituents of a toilet set are a brush tray, two scent bottles, a powder jar or bowl. ring stand, and one or two sminll vessels for holding cold cream ctc. A beautiful set in modern English cut crystal is here illustrated in which a pair of candlesticks is niso included.
Sometimes the whole equipment of a dressing table including hair brushes, etc., is hought to match. In silver, for instance, the articles can

Toilet Set. Modern English cut-glass toilet accessories look their hest on a polished mabogany dressing table, as illustrated in this photograph

and some, such as those of Reading and Sheffield in gold.
Tokens of the first period are generally thin pieces of copper. or other bnse metal, aliont the size of a sixpence, and forgeries are scldom met with About $20,(10)$ varicties of these quaint little tokeus are believed to have been struck, but only about half that number are extant. These are catalogued in countics, in a work by the late William Boyne, which may be consulted at any large public library.
The second and third periods exhibit better workmanship on more sulistantial disks of metal, and contain many private tokens, that is to say imitation tokens issued by collectors for exchange with other collectors. These private tokens are not currency tokens, and good anthorities, such as Charles Jye have noted and distinguished all the private tokens of the second period.

Other more or less spurious pieces of the two later periods are : The several serics of public buildings (notably at Coventry, Birmingham, and London, and in the scattered series with a globe on the reverse) made by coin dealers for sale to collectors political and satirical picces, such as Spence's and medalets-all easily diatinguishable by their designs and legends: mules, so called from each being struck from two dies never originally intended to lre combinel for one coin, non-local tokens manufactured in mass by die-sinkers to sell to traders, who profitably circulated the stuff without liability for redemption ; any apparent token not showing clearly the name of the issuer and the place of origin or redemption.
The most confusing of the spurious pieces are the mules of the second period. Expe-

Token. Obverse and reverse of tradesmen's copper coins issued in Great Britain. 1. London (Jewin Street) halfpenny, 1667 . 2. Swansea balfpenny 1796. 3. Cheltenham penny, 1812
rience, however, and a reference to Charles Pye's volume of plates, will soon train the collector's eye to reject spurious pieces. Mules of the third period are comparatively scarce. See Coin Collecting.

## Tomatoes: Growing and Cooking

## With Recipes for Some Tasty and Economical Dishes

This contribution deals first with the growing of this userul plant, the section including some lnfo mation about the diseases to which it is subje:t. Information about various ways of cooking the fruit follows. See Disbudding; Greenhouze; Kitchen Garden ; Omeiette; Salad; Snow Fly

This half-hardy plant, of which the fruits superphosphate of lime and liquid manure are used ns vegetables, has incrased enormously in popularity in recent years and immense quantitiee are sent to market. It can be grown to produce fruit throughout spring and summer under glass a nd out of doors in summer.
For summer fruiting it is raised from seeds sown in a heated greenhouse in February; the seedlings arc potted singly in small pots in a compost of loam and leaf-mould, and subsequently in 5 -in. pots in loamy soil. The plants should be grown in a temperature of about 50 degrees, the greenhouse being ventilated freely in mild weather; close, moist conditions will lead to failure.

Early in June tomato plants may be planted out of doors : a border at the foot of a sunny wall or fence is the most suitable. The soil should be dug deeply but not manured and must be trodlen firmly; tomatocs do not thrive in loose soil. The plants are set about 2 ft . apart and are supported by strong stakes. Al! side shoots must be rubbed off to restrict each plant to $\Omega$ single stem. When the first fruits are set, superphosphate of lime, at the rate of 2 oz. per square yard of grounul. should be applied and forked beneath the surface. The tops of the plants should be cut off when three or four bunches of fruit have set.

If the summer happens to be dry and warm tomatoes will do well in the open garden, but in a dull, wet season they are likely to prove disappointing.

For cultivation under glass the plants in 5 -in. pots should be re-potted into those 9 or 10 in . wide, or planted in a border of loamy anil not more than 12 in . deep and made firm by treading. The stems must be supported by stakes. The secret of success is to keep the plants as cool as possible and the soil moderately moist. Free ventilation is necessary. When the fruits are well developed
inay be given alternately once a fortnight. Great care in watering is necessary, especially if the tomatocs are p!anted in a border ; if the soil becomes sodden the plants are not likely to do well. To produce a crop of tomatoes in spring under glass, seeds should be sown in $\mathrm{S}_{\mathrm{t}}$ ptember.

There are innumerable varieties of tomato almost every scedsman hay his special sorts. Some of the best for cultivation out of doors are Essex Wonder, Bide's Recruit, Best of All, Ailsa Craig, Sunrise and A1. For cultivation under glass Princess of Wales, Abundance, Scarlet Beauty, and Earlicst of All are suitable. The yellow tomatoes, e.g. Golden Perfection and Golden Queen, are more suitable for the greenhouse than for out of doors.

Tomato Diseases. The chirf discases which affect tomatoes are black spot, sleeping dis ease, and yellow spot or stripe. Black spot attacks the eye of the fruit and causes it to crumple up and decay. Sleeping disease attacks the leaves of the plants. It causes them to lose their freshness of colour and droop, with the result that the whole plant ultimately perishes There is no effective remedy, and affected plants should be destroyed. The house in which the pest is found may be disinfected by a spray of a solution of sulphate of iron.
Stripe is mainly a disease of plants grown under glass, but it has been seen on those grown in the open in a position facing south and sholtered by a high wall. The symptoms are dark, vertical stripes on the stoms, brown sunken patches on the fruit, and brown shrivelled areas on the lraves. The disense frequently occurs in the seed bed, producing rapid destruction of the plants and necessitating fresh sowings.

The varicties of tomatoes differ very much in their susceptibility to disease. Generally
speaking, those varieties that show rapid, soft growth in the early stages are most susceptible to stripe Manure has considerable influence upon this susceptibility As with other diseases, excessive quantities of nitrogen and a lack of potash tend to lower the resistance power of the plant to the invasion of the parasite. The effect of too much nitrogen can be largely counteracted by an increase in the amount of potash. Sterilization of the soil by beat should be practised when an attack has occurred. Dry, airy conditions should be maintained under glass Soil infected by celworm ought to be removed from the glass. house and replaced by fresh soil.

How to Cook. Tomatoes that have been picked before they are ripe may be used to make chutney, but if it is desired to ripen them they should be placed in rows on a shelf in a warm room or where the sun can reach them. A little space should be left between each, otherwise they will become soft. Tomatoes too soft for serving whole, but only bruised and not over-ripe, may be used for stews and soups, but those that are to be served raw should be firm and unbroken Tomatoes give a good flavour to stewed beef and mutton To peel tomatoes without damaging the pulp, dip them into boiling water for a few seconds, and the peel will then come away casily They should not be left in the water too long, otherwise they will become partially cooked

Boiled tomatoes can be served either as a substitute for, or in addition to, a green vegetable. To prepare them, wipe them with a clean cloth, pull off the stalks, and drop them into a saucepan of slightly salted boiling water. Boil them slowly for 5 min . or a little longer, then drain them, place a few small pieces of butter on them, season with pepper and salt, and serve in a hot vegetable dish

Breakfast Dishes. Grilled tomatoes are excellent with bacon or sausages. Cut each tomato in half, season with pepper and salt, and place it under the grill. Fried tomatoes served on slices of fried bread are also a good brenkfast dish. Fry the bread in some beef dripping. then cut the tomatocs into halves and fry them in smoking hot fat until thev are tender. Selve three or four halves on each piece of bread, according to its size.
Tomatoes stulfed with fish can be made thus: Choose 1 lb . firm. even-sized tomatoes ;

Tomato. Fine fruit of the variety Sunrise
with a sharp knife cut a round piece from the stalk end of each, and scoop out some of the soft interior, reserving the pulp. Take the skin and bones from $\frac{1}{1} \mathrm{~b}$ cooked dried haddock, break up the flakes, and mix them with a large tablespoonful of boiled rice, a tablespoonful of chopped pickled gherkins. a chopped hard-boiled egg, 1 oz. melted margarine, the tomato pulp and seasoning to taste If the mixture is too dry, a little milk may be added Fill the cavity in each tomato with this stuffing, heaping it slightly on top Sprinkle over some browned breadcrumbs then bake the tomatoes in a moderately hot oven until they are tender, but not broken. Have ready a croûton of fried bread for each tomato, placing the latter on top and serving very bot
Devilled tomatoes, served on squares of grilled ham. are prepared thus: Cut 3 or 4 tomatoes into thick slices and spread each slice with a mixture made by seasoning a lump of butter about the size of a hen's egg with mustard, pepper, salt, and cayenne Bake the slices on a tin in a moderately hot oven and serve them as has been already stated.
thoroughly hot, put it into a pie-dish, and place the slices of cooked tomato on top Serve sprinkled with chopped parsley.

A savoury supper or luncheon dish is pro vided by tomatoes au gratin. To prepare it, mix 1 lb breadcrumhs with the sume quantity of grated checse, and shake a layer of them into the bottom of a greased fireproof dish. Cover them with some thick slices of tomato and a little chopped onion, add a sprinkling of pepper and salt, and continue these layers until the dish is full. About 2 lb tomatoes will he required. The last layer, which should be a fairly thick one, must be of cheese and crumbs. Put 3 or 4 small lumps of butter on top, and bake the whole in a hot oven until the top is browned. The dish should be sent. to table immediately it io ready
Tomato Chutney. To make this chutney, put 6 lb . sound tomatoes into a large enamel pan, break them with a wooden spoon, and then add $1 \frac{1}{2} \mathrm{lb}$. apples cut into quarters but not peeled or cored, 3 small onions peeled and minced, l oz. crushed mustard seeds, $\frac{3}{3}$ oz ground ginger, 4 oz . salt, a small teaspoonful of cayenne, and 13 pints malt vinegar.

Bring all these to
the boil, then simmer them until they begin to soften. Add 1 lb . moist sugar, stir until it dissolves, and then continue simmering until the tomatoes and apples are a soft pulp. Rub them through a hair sieve, stir them well, and bottle the chutney in two days' time

Tomato Jam. This vegetable jam can be made by wiping and stalking 6 lh tomatoes, cutting them into slices, and putting them in a preserving pan with $1 \frac{1}{2}$ pints water. Cook them slowly until they are tender, then rub then, together with the water in which they were cooked, through a sieve Put the purée
back into the pan with 5 lb sugar and the strained juice of six lemons
Bring the whole to the boil, remove the scum, add the grated rind of the lemons. and continue boiling for about 45 min . or until the mixture forms a jelly. Stir the jam occasionally to prevent it from burning, and skim it whenever necessary. When it is sufficiently coo! turn it into pots, tie it down when quite cold and store in a dry, cool place.

Tomato Ketchup. For this relish 4 ib .
 cloves, and allspice, a gill of vinegar, and a little salt are netded Cut the tomatoes in halves, place them on a dish with the cut sides upward and sprink!e them with salt. Leave them thus for 24 hours, then put them into a pan and simmer them until the skins become loose Strain them through a coarse sieve. and to the liquid add the minced onion, the ginger cut into small pieces, and the pounded cloves and allspice. Turn all into an enamel pan, and boil them unti! they are reduced by one-third Add more salt, if necessary, and when the ketchup is cold strain it into bottles Store it in a dry, cool place.

Tomato Omelette. A savoury omelette, with tomato and onion as flavouring ingredients, can be made thus: Melt $\frac{3}{4}$ oz. butter in a small frying pan. and fry in it a slinned tomato cut into slices and 1 teaspoonfu! chopped onion. In the meantime separate the yolks from the whites of 2 eggs, beat up the former, adding salt and pepper to taste and a teaspoonful of grated cheese Whisk the whites with a pinch of salt to a stiff froth, and fold them lightly into the yolks.

Melt ${ }^{3}$ oz. butter in an omelette pan, and when it is hot pour in the egg mixture, stirring it round to prevent it from sticling to the bottom of the pan. When it begins to set, place the hot tomato and onions in the centre, and linish the omelette in the usual way.

Tomato Sauce. Tomato sauce for serving in place of gravy may be prepared with fresh or tinned tomatoes. Weigh out $\frac{1}{2} \mathrm{lb}$. tomatoes, wiping them and cutting them into slices if they are fresh; then put them into a saucepan with an onion and a carrot, pceled and sliced, $\frac{1}{2}$ oz. margarine, $1 \frac{1}{2}$ gills stock or water, $\frac{1}{4}$ teaspoonful celery seeds tied in muslin, a teaspoonful sugar, and pepper and salt to taste. If tinned tomatoes are used, only 1 gill stock will be required
Cook the whole slowly until the vegetables are tender, then take out the celery sceds and rub the sauce throngh a hair sieve. Put it back into the sauce pan, thicken it with a teaspoonful of corn flour mixed to a smooth paste with a tablespoonful of oold water, and then let it boil slowly for 5 min . stirring all the time.
Tomato Soup. To make tomato soup, put into a frying pan 2 oz . ham or bacon, cut into dice, and 1 oz. butter. liry in this for 5 min . a carrot, a turnip, 3 sticks of celery or a little celery seed, and a bouquet garni ; then add 2 lb . ripe to matoes, or for pref erence 2 lb . tinned ones. Let all simmer for 20 min .; afterwards remove the bouquet and pass as much as possible of these ingredients through
a hair sieve. Have ready at boiling point a of 40 . Predisposing pint of good, well-scasoned stock, which should be thickened with $\frac{1}{2}$ oz. corntlour made into a thin paste with some stock. Add the pure to the stock, and, if required, a squcéze of lemon juice and some more seasoning. Boil up and simmer for 10 min ., stirring well. Fresh tomatoes may need rather more stock than the anount mentioned.
TON. This measure of weight consists of $2,240 \mathrm{lb}$. or 20 cwt . It is used for weighing coal and other heavy materials. See Avoirdupois Weight.

TONGS: For Household Use. Tongs arc appliances for gripping and moving any object with safcty or conifort, and without soiling the hands. In their general form for louschold use, in moving coal from the scuttle to the fire, they consist of a pair of levers pivoted at one end, or with an open spring loop, their length depending upon the purpose for which they are required. The longer varietics have a handle fitted at the end at which they are pivoted. These are now seldom used, but are still seen in ornamental brass and stcel as a decorative finish to period fenders or curbs of the same metal. Tongs are a component part of a set of fire irons. (See page 458.)

TONGS: For Metal Work. Special tongs are used to hold iron pipes in gas and hot water fitting. The gas tongs illustrated in Fig. I is a convenient tool for gripping gas piping without damaging the pipe. It is made of forged stcel and hardened at the gripping end. One end is curved to encircle the pipe, while the other end is short and has a sharp, square inner edge which bites into the softer metal of the pipe, thereby holding it securely. Tongs of this type are made only for one size of pipe.

A further application of tongs is found in the blacksmith's trade. These invariably take the general form of those illustrated in lig. 2, the salient feature being that their handles arc long compared with their gripping ends, in order that great leverage, and therefore gripping powers, may be applied. The larger of the two pairs illustrated is made primarily
of 40. Predisposing decayed or broken teeth, badly fitting dental plates, excessive smoking, and anything that scts up inflammation or irritation.

Acute inflammation or acute glossitis is most often caused by wasp stings, or stings and bites of other insects ; also by burns and scalds, and by wounds which become scptic. Treatment would be directed by a doctor.
The commonest cause of chronic inflammation are syphilis, tobacco smoking, drinking alcohol not suffiattaclis of acute inflammation. to be held in the mouth. ciently diluted, decayed tceth, and previous

Uleers of the tongue may arise from injury or dyspepsia. The former variety is generally due to decaycd teeth or badly fitting artificial teeth. The ulecrs due to dyspepsia are generally on the tip and upper surface.

Wounds are most commonly caused by jagged teeth, but may be caused by the person biting his own tonguc, or by instruments or weapons. If bleeding is rery free, try to grasp the wound firmly between the fingers while awaiting the doctor. Otherwise give ice

Tongue as an Aid to Diagnosis. The state of the tongue varies in different diseases, as the following particulars will show: In chronic dyspepsia the tongue is often swollen. flably, and coated with fur, which may be white yellowish brown, and sometimes black. In

for gripping Hat picces of metal and enabling the latter to be held sccurely on the surface of the anvil while forging is in progress. The smaller pair inds its greatest use in gripping chisels for the purpose of cutting metal by that tool. In this par ticular case the chisel would be held in position by an assistant while the blacksmith applied the hammer. See Casting; Forge: Pipe; tongue is coated with a thick white or Plumbing; Spanner; Wrench.

TONGUE : Its Diseases. The tongue is composed of a number of different muscles the fibres of which run in various directions. Over the surface are scattered numerous small, reddish, pointed projections, which have to do with the sense of taste. The chicf duties of the tonguc, in addition to acting as the organ of taste, are to assist mastication, swallowing, and the pronunciation of words.
Amongst diseases of the tongue is cancer, which is about six times as common in men as in women, generally occurring about the age
acute gastritis the fur is white, but does not extend to the tip and cdges of the tongue, which are bright red. In prolonged constipation the

'longued Joint. Fig. 1. Plane used in preparing tongue. Fig. 2. Use of grooving plane
however, needs longer soaking and very slow cookiny. Pigs' tongucs are prepared in the same way as sheep's tongues. Cold tongue, cither alonc or with salad or cold cooked ham, makes a particularly good luncheon dish, and, like most other cold meats, can be made into sandwiches. It inay also be potted.

There are various ways of serving cooked tongue when a hot dish is needed. If minced, combined with breadcrumbs, and heated up, for instance, it nakes excellent savouries. Pass the tongue through a mincing machine; then pound it with about one-third its quantity of breadcrumbs and ewough sauce to bind it. Season it with caycune and a little lemon juice and rub the whole through a siece before heating it over a slow fire. When it is thoroughly hot, pile it high in some newlyfried cases of bread and garnish each savoury with a little parsley

Another incthod of heating up cold tongue is to cut it into neat slices, season them to taste, sprinkle them with lemon juice, and let them stand for a while before dipping them in egg, coating them with breadcrumbs and then frying them to a golden brown colour in smoking hot fat. Serse them at once, garnished with parsley and thin slices of lemon. See Calf's Head ; Ox Tougue ; Potted Meat: Shecp's 'Tongue.

TONGUED JOINT. This is a joint in which a sma!l projection along the length of one part, known as the tongue, fits into a slot or groove in the other part and so completes the joint. A common application is found in tongucd and grooved floor-boards. This material is finished on one side and generally measures in width 4 in . to 5 in . The average thickness is nominally 1 in., but actually it measures slightly orer $\frac{\pi}{8} \mathrm{in}$. Thicker boards are available, but are seldom used except in high-grade work or where very considerable strength is needed, ordinary 1 in . tongued and grooved flooring being guite satisfactory for most domestic work. The amateur will find that this elass of timber with its tongued
joint is extremely useful for a great many purposes.

In the construction of tongued joints, a tonguing and grooving plane is usually entployed, such as that illustrated in Fig. 1, which has variously shaped irons and adjustable fences, and makes grooves $\frac{1}{i n}$. in width. On one side is an adjustable fence composed of a strip of hardwood which locates the position of the groove in respect to the working face of the material.
The niethod of using this plane, as illustrated in Fig. 2, consists of securing the work in $n$ vertical position on the bench between blocks of wood or by holding it in the bench vice. The plane is rested on the upper surface of the work $w$ ith the fence resting against the face, and worked backward and forward in the usual way. The tongue can be made with the same plane, and finished by the regular tonguing and grooving plane or matching plane, specially prepared for the purpose The plough plane is also used for this class of work.

Tongued joints are found in many kinds of woodwork, particularly in cabinet work and the better quality joinery. Examples are also seen in metal-work. In both cases they are akin to the feathered joint, except that, instead of using a separate strip and sinking it into a groove in cach piece of material, the joint is formed from the solid. For woodwork, the tongued joint forms one of the best methorls for jointing the edges of long picces of material, and when well cramped up and supported by cross battens it makes a particularly rigid structure. See Joint; llane.

TONIC. Drugs or mixtures of drugs which increase the efficiency of the body as a whole, or of any of its systems, are called tonics. Thus there arc nerve, blood, heart, and general tonics. The following are cxamples of a tonic designed to brace up the nervous system :

## Tincture of nus vomica <br> Spirit of chloroform.. <br> Water, enough to malie <br> Dose for a grown person : I tables oz."

 a day after meals.Solution of strychnine hydrochloride.
poonful 3 times Iron and quinine citrate
Spirit of chloroform.
Tincture of calumba Water, enough to mak Water, enough to make ... 6 o\%." Make into a mixtıre. Dose: $\frac{1}{2}$ to 1 tallespoonful
The following arc examples of tonics directed towards improving the quality of the blood:

Water, enough to mais 102.

Make into a mixture. Dose for a $\downarrow$ rown person: 2 tablespoonfuls 3 tines a day after meals. Sulphate of iron
 8 oz.
Make into a mixture. Dose for a grown person: $\because$ tablespoonfuls 3 times a day. This prescription is appropriate when there is any tendency to coustipation
The following is an example of a bitter tonic often very valuable where the patient's appetite is capricious and he is run down:

| Tincture of nux vomica | 2 drims |
| :---: | :---: |
| Iron and quinine citrate | 2 |
| Dilute phosphoric acid | 4 |
| 'Tincture of orange | 2 |
| Chloroforn water, enough |  |

Trincture of orange
Chloroform water, enougli $i_{0}$ make
Make into a mixture. Dose : 1 to 2 teaspooniuls
an hour before cach meal. ? an hour before cach meal.
The following is an example of so-called simple digestive tonic mixtures:

$$
\begin{aligned}
& \text { Tincture of cascarllla } \\
& \text { Dilute hydrochloric acid } \\
& \text { Syrup of orange } \\
& \text { Water, enought to naike }
\end{aligned} .
$$ 2 to 4 teaspooniuls 3 times a day.

One of the best all-mound tonics for general debility is Easton's syrup, dose, $\frac{1}{2}$ to 1 dram

3 iimes a day alter meals. No tonic shouid be taken for longer than a month or 6 weeks at a stretch, as otherwise it may upset the digestion, also losing its original cfficacy.

TONING : In Photography. Toning is a method of chinging the colour of a photographic print after development and after or luefore fixing. Whether on P.O.P. or bromide paper, all prints which include a silver salt in the light sensitive film can be toncd. Prints made on P.O.P. by daylight invariably need toning, as otherwise the colour is not pleasing. Prints made on gaslight or bromide papers are only toned when it is desired, from black and white to warmer colours or tints.
Nany varicties of P.O.P. have toning chemicals included in the film on the surface of the paper, so that when placed in the fixing bath toning is carried on automatically at the same timc. These are known as self-toning papers (q.v.). With the non-toning printing-out papers the toning process may be combined with the lixing, or the two operations may be carried out separatcly. The latter is the better course, as when a combined bath is used there is a risk that the print may be removed from the bath before fixing is complete because the desired colour has been obtained. Thus prints, not being sufficiently fixed, will not be permanent.
Toning of P.O.P. This is practically always carried out with a salt of gold, although warm black tones can be obtained by using platinum compounds. Both agents are extremely expensive, but are only required in minute quantities. The gold is used in the form of gold chloride, sold in tubes containing 15 gr.
The following are standard formulae for gold toning the common gelatino-chloride papers :

Gold Stock Solution
$\begin{array}{llllllll}\begin{array}{l}\text { Gold chloride } \\ \text { Water }\end{array} & . . & . . & . & . . & \text { to } & 15 \mathrm{gr} \text {. } \\ 15 & \mathrm{oz}\end{array}$
Sulphocyanide Stock solution
Wamonium sulphocyanide .. $\quad$. 100 gr .
For use, mix in the following order:
Stock solution 13
Water
Stock solution $\ddot{A}$ 20 oz
$2, "$
A bath recommended by the Ilford Company for warm tones is the following: Stook Sulphite Solution
Sodium sulphite in $\begin{aligned} & 15 \mathrm{gr} \\ & 10 \mathrm{gr}\end{aligned}$
The toning bath is made up as follows :
Stock solution A
stock sulphite solutiou
Nitock solution 13

Mix in the order given. The sulphocyanide toning bath should not be used more than once. If a large number of prints are being toned at the same time, it will be found necessary to strengthen the bath when toning becomes slow. This may be done by adding small quantities of the following solution, which must be made up as required :

## Water

Stock solution B
50 oz
1
5
All gold solutions work best after they have been allowed to stand for at least 24 hours. This toning bath will give red to purple tones. Before toning P.O.P. in this or other baths, prints must be well washed in water until the washing water shows no trace of milkiness. At least six changes of water are required if running water is not used. This washing removes the soluble silver salts from the paper, which would otherwise act on the gelatinc and produce discoloration.

In hot weather it is important to harden theprints before toning. They should be immersed for 10 min . in the following bath and washed thoroughly for 10 min . after hardening. The employment of this alum and salt bath will secure regularity of tone.
Common salt
Alum
(i) $20^{1 \frac{1}{2}}$,

Toning P.O.P. may be carried out in weak daylight well away from a window. A large porcelain dish should be used and kept for this purpose only. Prints are imnersed in the solution one by one, care being taken that air bubbles do not eling to their surfaces. The prints must be lept in constant motion and must not be allowed to stick together. If these precnutions are not observed, uncqua! toning or stains may result.

While in the bath the prints must be carefully watched, and a little experience is necessary to determinc when they should be removed. The colour gradually changes to brown, then to purple, ending with a slaty blue. The shorter the time of toning the warmer or redder the finished print, the longer, the colder or bluer will be the final colour. A cold solution is liable to give muddy tones, whilst a bath which is too warm will give pinkish prints. The temperature should be about $65^{\circ} \mathrm{F}$. A bath containing too much gold hastens toning, but gives muddy tones; while a slow bath, due to deficiency of gold or cxcess of sulphocyanide, gives pinkish tones.
When toning is judged to be complete, prints should be washed at once in running water to prevent continuance of toning. The quickest method of stopping toning is to immerse the prints in a weak solution of sodiun sulphite $5 \mathrm{gr} . \mathrm{per} \mathrm{oz}$. of water.

Poor negatives will never give good prints on gelatino-chloride P.O.P. Defects in the linished prints are due to the following causes : Handling the prints before toning with moist or greasy fingers will cause red patches. Allowing prints to stick together in the toning or fixing bath, or insufficient washing after the hardening bath, or other stages, causes unevenness of tone. Small quantities of hypo introduced into the toning bath will cause brown discoloration or coniplete absence of toning. It is, therefore, advisable to complete toning and washing before begimning fixing or otherwise handling hypo solutions.

## Combined Toning and Fixing.

If sufficient care is talien to ensure complete fixing, combined toning and fixing will give good and pleasing colours. The prints must be made distinetly darker than when separate toning is carried out, and placed face downward without previous washing, as distinct from the careful washing of separatcly toned prints, in the combined bath. They must be left in the hath at least 7 min . to ensure lixing : they should not be in more than 10 or 12 min . Following is a good formula :

Dissoive in hot water in the order given and prepare at least 24 hours before use, shaking well. After standing, decant the clear liquid, allowing $\frac{1}{2}$ oz. for each 1 plate print. Throw away after use. Keep the prints moving.
Sulphide Toning. Gaslight and bromide prints may be toned in a variety of colours. The most popular process is the sulphide method, because of its simplicity, good colours, and permanent results. After fixing and washing, bromide prints should be dried before toning by the sulphide process.

The print is first bleached in the following bath, which can be made up as a stock solution and used until its bleaching powers fail:

> Potassium ferricyanide
> Potassium bromicle
> $\because$ to $20 "$

The solution should be stored in a yellow or lirown bottle away from the light. The print bleaches to a faint yellow in a few minutes in this bath, is then rinsed well, not washed too long, and put into a sorlium sulphide toning
bath, which restores the image in fine brown and sepia tones. Make up a stock solution of 2 oz. of pure sodiun sulphide (white, not green crystals), in 5 oz . of water. For use, take $\frac{1}{2} \mathrm{oz}$. of this solution and add 10 oz . of water. The print is toned rapidly, and no variation in colour is obtained by leaving it in after the image is completely redeveloped. Wash thoroughly for about 15 min . in running water. After use, the sulphide solution must be thrown away.

Variations in colour with this process can be obtained by first bathing the print in the sulphide solution, then washing, bleaching in the ferricyanide solution, and finally redeveloping in sulphide solution. To get deep sepia and warm black tones the process is carried out as first described, with the exception that bleaching is stopped before it is complete. The more of the original black image left the deeper will be the final colour.

All the processes described above for bromide papers are applicable to the toning of lantern slides. See Developing; Fixing; Negative; Photography ; Printing.

TONSIL. The tonsils are two sinall glandular bodies situated on each sidc of the back part of the mouth, at its juncture with the throat. Their main function appears to be that of trapping toxic matcrial as it passes backward from the mouth. See Adenoids.

TONSILLITIS. Inflammation of the tonsils is of several types and occurs in an acute and a chronic form. The former occurs inost commonly in young people during spring or autumn. People of a rheumatic tendency are more liable to the disease than others. The most common causcs blamed for exciting an attack are exposure to cold and damp or to overheated and impure air.

The earliest symptom of acute catarihal tonsillitis is pain when swallowing. If the tonsils are examined they will be scen to be red and swollen, dry at first and then covered with a layer of mucus mixed with pus. An attack scldom lasts more than a few days. It is often associated with pharyngitis, and may be followed by inflammation of the middle ear.

The symptoms of acute follicular tonsillitis are more severe. The patient should be kcpt away from other members of the family, as tonsillitis is more or less contagious, and it is not always easy at first to distinguish between an attack of this discase and diphtheria. He should not be allowed to talk or to swallow anything but liquids or semi-solids.

To prevent relapses the mouth and teeth should be cleansed morning and night, some antiseptic mouth wash being used. A good protective measure is to hathe the neck in cold water.

Chronic tonsillitis, popularly known as enlarged tonsils, is usually the result of repeated attacks of the acute form. It is met with mainly in children from 5 to 15 years of age, and is more common in boys than in girls.

Usually the affected child breathes through the mouth, keeping it always open, in consequence of which he has a stupid expression. At night his breathing is noisy and irregular, and he is often the victim of nightmare and night terrors. Cough may be troublesome at night. The patient is especially liable to attacks of nasal catarrh. He continually hawks up mucus from the throat. At times swallowing is painful, and both the sense of taste and the sense of smell are often defective. The bearing also is frequently impaired, and this may develop into complete deafness.

In very slight enlargement, measures to build up the health may be effective in subduing the symptoms and preventing the development of the enlargement. But the correct treatment of diseased tonsils is to have them removed. See Adenoids; Quinsy.

## Tools for the home Worker

## A Selection to Suit All Ordinary Requirements

This contribution gives some detailed advice on the selection and care of tools for simple wood and metal work. Further information about individual tools will be found under such specific headings as Chisel; Plane; Saw. See also Amgteur Carpentry; Bench, etc.

Prepared collections of woodworking tools
ften contain some which are seldom used by often contain some which are seldom used by the beginner, and it is better for the amateur to start with the fow indispensable tools and add to them gradually as he acquires dexterity and experience in his hobby. The outfit desirable for simple carpentry will also be adequate for most of the odd jobs which fall to the handyman, if supplemented by a few metal working tools. A start could be made with the following, and if desired only those marked with an asterisk (*) need be procured at the outset.
${ }^{*}$ Haminer, Fixeter pattern, $\frac{2}{2} \mathrm{lb}$.
*Pane" ball peine, 1 lb .
*Panel' saw, 24 in .

- Tenon saw, 15 in .
*Screw driver, London pattern, 9 in.
Ratchet screwdrlver, 3 in. blade
${ }^{2}$ Gimlets
${ }^{2}$ Bradlawls
-Carpenter's brace
*Set of centre bita; * 3 twist bits; turnscrew bit countersink for wnod, rose bit countersink, flat countcrsink bit for iron, auger bits, $\}$ in., 是 in., $\frac{1}{2} \mathrm{in}$.
- Steel rule, 2 -ind 24 in.
-Carpenter s square, 8 in
Spirit level, 10 in
Marking gainge
Compass saws (handle and 3 blades)
Compass saws
Coping saw and spare blades
Chisels, firmer, *t in. ; $\frac{2}{6}$ in.; $\frac{1 \mathrm{in} . ; 1 \mathrm{in} \text {. }}{\text { Cong }}$
- Mallet, joiners
- Metal vice 4 in. jaws; C'arpenter's bench vice

Spokcsliave, metal
Jack plane, 2 in. iron
-Smoothing planc

- Nail punch

Putty knife
Glass cutter (whecl)
-Glue pot
*Oil stone in case

- Pincers, Lancashire, 8 in.

Wing compasses, 8 in.
Hand axe, American pattern
Combination pliers, 8 in.
Centre punch
Hand drill and set of twist drills ( $\mathfrak{r}^{1} \mathrm{in}$. to l in . rising by $\frac{y}{y}$ in.) in metal holder

Broaches, $\frac{1}{}$ in. $\frac{1}{2}$ in., and 1 in.
Broach holder, adjustable
Files: *Saw fle, 6 in.; hand filc, 8 in. basta
cut

Cold chiscls, that chipping, ${ }^{*} 8 \mathrm{in}$. by $\frac{1}{\frac{1}{2}} \mathrm{in}$; 16 in . by ${ }_{8} \mathrm{in}$.

Mason's hammer 2 lb
Soldering blt, adjustable, 1202.
Tinman's snips, straight, 8 in.

- Adjustable spanner wrench, 10 in.

Adjustable pipe wrench
Set of fixed spanners
Tools should be kept in a simple rack or in shelves adapted to each type or group of tools. Orderliness preserves the tools and saves tine.

In the article on Amateur Carpentry will be found helpful information about the lay-out of a workshop and the arrangement of a bench. Should the home worker decide to make his own bench he will find the necessary plans and details in the article Bench. As a makeshift a stout false top can be used on the kitchen table if the latter is of substantial construction. The top should be of 1 in . T. \& G. flooring or similar stuff, and can be cramped to the table top when in use by a pair of 6 in . G cramps. A piece of board can be interposed between the screw of the cramp and thc underside of table to prevent marking the latter, and a recess might be formed in the upper side of the false top to take the jaw of the cramp.

With the kit of tools enumerated above the handyman will be equipped to tackle all sorts of repairing jobs about the home, and to do simple constructional work. Since timber can readily bc obtained in a prepared state, the amateur will not be called upon to do much planing. If he further arranges for his
boards to be ripped to width at the timber yard (in cases where a stock width board will not work in) there need be little sawing but that involved in cross cutting to the desired dimensions.

Moulded sections in a wide and usefus variety can be obtained, and turned sets of legs suitable for tables, cabinets, or stools The stiles and rails for a panelled door, e.g for a cupboard, can be made from ready grooved material, the groove being of a size to take stock plywood. The legs for a cabinet can be purchased with grooves formed in them, saving much labour to the novice. These refinements permit of quicker and easier construction, and avoid the purchase or use of tools like the moulding planes, plough, fillister. etc. Joints can be simplified by the use of dowels to a considerable extent.

The woodworker as his skill increases may desire to undertake cabinet making and perhaps inlaying, marquetry and similar ornamental work. The tools for these are detailed in the specific articles on the subjects mentioned. Woodcarving also demands tools of a special nature.

Apart from these special requirements the worker can well supplement his tool kit with the following:

Rip saw, 28 in., 4 points to incl,
Hand saw, 26 in., 7 points to inch
Bow saw
Trying Plane, 24 in .
Rebare planc
Side fllister
Slough
Mortise chisels, is in., is in.
Mortise gauge
Firmer gouges, $\ddagger$ in., $\frac{1}{2}$ in.. in
Saw set and assorted saw files
Sash cramps (2)
Plunb rule
Plumb bob and line
Bevel square
Half round rasp, 8 in
Mitre box
In place of the scparate rebate, fillister and plough planes mentioned above, the worker could buy a combination tool with an assortment of cutters.

## Tools for Outdoor Work

For outdoor work the following will be handy : farmer's saw, for cross cutting rough wood ; Kent axe, draw knife; beetle or maul, for driving posts, splitting timber, etc.; one or two alngers and handle; brick trowel, 10 in . ; pointing trowel, 5 in .; sledge hammer, 3 lb . If a permanent workshop is available it will pay to invest in a leg vice, which stands on the floor and is screwed to the bench. A small nnvil will be invaluable for riveting operations, and can be had to rest on bench, or with a spike to knock into a wooden block. The latter is useful in dealing with a job which cannot be taken to the bench. The amateur who wants to do a little forging should refer to the article on that subject, where the necessary implements are detailed. A grindstone or some type of bench grinding machine will be needed to kecp the cutting tools in proper order.

The tools used in wood turning are dealt with in the article on that subject, while the amateur metal worker will find appropriate tools listed under such headings as Lathe; Metal Turning and Metal Work. The cutting of screw threads by hand and machine demands special tools, about which the relevant information is given in the articles Screw Cutting: Stocks and Dies. If any considerable amount of metal work is done it is well to include in the tool kit a small steel set square, spirit level, scribing block, surface plate and
sliding caliper gauge. A stecl rule about 12 in long is convenient for this worl:

Care of Tools. Ordinary wooden Irying, jack, and smoothing plancs are made of becch. In making a choice, the direction of the grain should be carefully noted; it should run straight along the side, and the annual ringe should be of large radius curving towards the sole. with the medullary rays vertical The irons should be double and with parallel sides, with the back iron well arched, and should fit snugly in the mouth. The menth of a new plane should be stopped with putty and the opening filled with linsed oil and left until line globules of oil appear on the ends, the surface being wiped over from lime to time. Iron blanes of the above type should have double irons, those fittel with single irons being of !ittle use for serious work.

Mach trouble can be avoided by tho annateur in planing if the right soit of plane is used for the work in hand. The smoothing plane, for instance. should on no account be used except lor taking the finishing slavings off a previously planed surface. This plane is short and liglit, the mouth is smail, and the irons should be set close together ; it is not intended to true a surface in the sense of making it level, but to render the trued surface perfectly smooth.
For most gencral purposes a correctly adjusted jack plane, either wood or metal, is capable of doing all the work the annatcur is likely to tackle, but, even considered as a general-purpose plane, there is a correct way of holding it, and several ways of adjusting it to suit particular uses. The shavings from a correctly set and properly sharpened jack plane shoulcl be parallel and have an even curl, and the sound of the cut is easily recog nizable by the experienced woodworker. The necessity of a sharp cutling edge is very important in the case of the simaller planes, such as the rebate, plough, beading, mou!ding, and similar tools, and it is not a simple matter to sharpen the sma!! curves while retaining the correct shape

## Choice and Care of Saws

Saws of all kinds should be of the best quality obtainable. The skew-back hand or lip saw with the blade extending well into the handle is generally preferred, as it is more under control and is not liable to work loose in the handle. The brass or iron back on a tenon saw should be heavy and made of stout inaterial, and it should be noted that its own weight ought to be sufficient to carry it through the wood. A good handsaw can be tested by the sound when struck sharply with the finger nail, and it should be possible to bend the blade to a semicircle without affecting its straightness

When not in use. tools should be kept in a drawer, cupboard, or chest, and arranged with a special place for each. When they are on the bench care should be takell that the cutting edges do not come into contact with other tools or with the bench. The planes should be rested on a thin !ath placed across the bench. The wedges should be carefully driven in with a mallet, but the same tool should not be used to adjust the iron. The mallet is the best tool to use when loosening the irons. The sole of the plane should be frequently wiped over with linseed oil, and to protect the surface umplaned wood should be brushod over hefore planing to remove grit, etc. The cutting irons of rebate, beading, moulding, and similar narrow planes are liable to damage if allowed to lie on the bench, and these tools should be put away directly after use
Saws should be hung up when not in use, unless there is a special place for them; they should be frequently wiped over with vaseline, lallow, or a good lubricating oil. If they are
not kept in a chest or cupboard properly supporied, it is a good plan to cover the cutting edges with a strip of wood in which a groove has been sawn. Chisels should be placed down on the bench after use with the bevel side downward as there is less risk in this way of the edge getting damaged but the better plan is to have a rack on the bench, conveniently placed at the back so that tools being used on a piece of construction can be placed out of the way of damage. The handles of chisels used for mortising soon become bruised on the ends, and unless the smal! chips are trimmed off they will act as wedges and split the whole handle. It is useful to keep a coarse-cut file handy for trimming the end of the wood.
On no account should wood-boring bits of any lind be allowed to lie on the bench after use ; they should be placed in a rack or drawer. The try square is another tool requiring careful usage, as it soon gets out of truth if allowed to fall on the floor or get knocked about. Quite as much care is needed with metal.
working tools, although they are as a rule heavier and less liable to damage. Tool racks should be provided for the metal-working bench, not only to prevent damage to tools, but in order to be able to find them when required. Metal clips are obtainable for attaching to the wall, but wooden racks or other suitable means of support are easily made. The amateur craftsman should make a point of providing a place for each tool and sec that it is in its place when not in use
'Tools such as a hand-drill need a special place in the tool box or cupboard, and shonld not be buried among all sorts of heavy imp!ements Smaller toola, well smeared with grease, caı be kept in a long narrow tin biscuit box Drills, reamers, broaches, taps, etc., are best kept scparate in Hat cigarette tins, each sort in a special box. Only one layer should be accommodaled in the i , or the cutting edges will sufler damage by contact with tools above The tools if greased will be free from rust, and the arrangement mentioned will enable any one to be found quite readily

## Tool Chest : How to Construct

## With Working Drawings for a Simple Type

Our article on the receptacle for the tools used by the amateur carpenter or mechenic is complenentary to the proceding one dealing with the selection and care of tools themselves. It is followed by a contribution describing how to make a tool cupboard. Reference should also be made to the entries on the various too's and processes
A chest large enough to take a complete lengths should be left as glued up. Tho width equipment is shown in Fig. 1. There are six of the back piece should be reduced to 19 in . shallow she! res, and the bottom is divided into the sides to the same width, and the front compartments. Half the front is hinged for greater convenience in getting at the shelves, and certain of the tools are attached to the inside of the lid. The wood should be sound yellow pine: if ordinary vellow deal is used it should be free from linots.
The main dimensions of the chest are shown in the sectional plan and clevations in ligs. 6,3 , and 4. The carcass is of 1 in . wood (linished size). and the wood should be at least $1 \frac{1}{8}$ in thick before planing. It saves much labour and time to have the wood machine-planed
The carcass of the chest, as in Fig. 5 , is made to inside measurements of 34 in by 18 in . by 18 in ., but as it is impossible to obtain pine or deal of this width it will he necessary to glue up 2 boards. Allowing for waste ends, 16 ft . by 11 in . by 1 in . and the same length of 9 in . by 1 in . boards will be required, with the top and falling front Hap.

First prepare the boards for glacing by planing up one side and edge, cutting the front and back pieces to $36 .!$ in. and the end pieces to $20!\frac{1}{2}$ in. long. Fach joint should be tested before glucing, as it is important that the join should be perfect. The pairs of glued boards shou!d be placed between cramps and left until the glue has set. If the wood is already machineplaned to the correct thickness, the elges only need be planed, but care nust be taken to have square edges to ensure the pieces having a true surface when glued.

The best method of joining up the sides of the carcass is by dovetailing, as in lig. 5, but an easier and al. ternative method is to use the lock corner joint. In both cases the
to $10 \frac{1}{2} \mathrm{in}$. wide. First maik off 17 in . each side of a centre pencil mark on the wood on both the back $A$ and front 13 pieces ( $\Gamma$ igs $3-5$ ), and then mark another line 1 in further along. The end pieces $C$ are marked ! in. each side of a centre line and then marked 1 in . further along.

There are two methods of inaking the clove tail joint. That in ordinary use by the cabi net maker consists of marking out the sockets and sawing them complete. The saw cuts are placed on the ends of the front and back pieces in turn, the tenon saw placed throug! the cut and marked on the ends of the wood as in l'ig. 6. This is a good method in the hands of a skilled worker, but the amateur who is not practised in making the joint is arlvised to proeeed with the cutting of the pins first.
In the former method the pins are cut out by sawing on the waste side of the saw cuts and the waste cut out of both pieces with a chisel. In culting the pins on the ends of the back board, first set off two $\frac{1}{2}$ pins top and bottom and then space out the remainder; $s$ is suggested as a reasonable number. The amount of the slope need not he more than $\frac{1}{8}$ in in the 1 im . "idth, and it may be less in hardwood. The easicst way of marking out a number of pins is to cut out. a dovelail marker from a piece of tinned sheet or brass as in Fig. 7. This is placed on one set of marks, and a pencil line drawn each side. When the marks have been made, the sa w should be placed in each case on the waste side of the line and carried down to the correct depth. The waste is cut out witha chise from the narrow side first, and the remaining portion

cut from the other side, taking care not to allow the chisel to go below the line.

The pins are placed upright on the side of the end pieces so that the widest portion of the pins is on the inside of the two lines, as in Fig. 8 A sharp pencil is drawn along the sides of the pins, and then the waste side of the pencil lines is sawn down with the tenon saw. In cutting out the waste with a chisel, commence about $\frac{1}{8} \mathrm{in}$. from the back with a chisel measuring about half the size of the widest part of the opening, and cut a hole as in mortising, taking it half-way through. Turn the wood over and repeat, the remainder of the wood being cut out afterwards with little risk of breaking the sides of the sockets. The bottoms of the sockets as well as the pins may be slightly undercut in the middle, but great care must be taken not to go below the lines on the outside of the wood.

Other Methods of Joining. The alternative lock corner joint is marked out by setting off equal spaces of 1 in . or more on the ends of all picces, and before sawing it is important to mark very distinctly those portions to be cut out and to saw on the waste side of the line. Instcad of joining the corners in either of the above methods, the side picces can be accurately cut to 18 in . wide for a height of $10 \frac{1}{2} \mathrm{in}$. and 19 in . for the remainder ; the front and back are in this case glued and screwed to the ends. Although this method will be strong, it is not зо satisfactory and does not look so well, but it certainly saves time.
The sides and ends are now ready to fit together, but before this is done the method of securing the bottom $D$ must be considered. The easiest way is to fit the wood exactly as in Fig. 4, after the work is glued up, and then either screw or nail it in. The nails or screws will be covered by the plinth moulding. The most satisfactory method is to tongue the edges of the bottom board and plough a corresponding groove in the sides and ends, as in Fig. 9, so that the wood can the glued only. If this method is followed, the work of rebating the edges of the bottom and grooving the sides and ends of the carcass must be done before the work is glued up. The bottom board is accurately finished to $34 \frac{1}{2}$ in. by $18 \frac{1}{2} \mathrm{in}$. and gauged $t$ in. from the top and from
the edges, and the waste is removed with a rebate plane or fillister A gauge line of $\frac{3}{5}$ in., followed by another of 1 in, is made from the bottom edges of the back, front. and ends of the case, and the groove made with a plough plane.
The joints of the carcass can now be fitted together, but in driving the sockets home, a piece of waste wood should be placed on the ends to avoid damaging the material. The wood for

Fig. 4
the falling Hap is now prepared. and accurately fitted in position as at E , and strengthened at the ends with two $8 \frac{1}{2}$ in by 4 in by $\frac{3}{4}$ in. pieces glued and screwed on, the flap being 34 in by $8 \frac{1}{2}$ in by 1 in. It is joined to the front B by two 2 in . by $\frac{3}{2}$ in brass butt hinges, let in flush with the surface.

The bottom plinth or moulding should be prepared from $\frac{3}{5} \mathrm{in}$. wood and planed to $3 \frac{1}{4}$ in wide. The front and back pieces G are $37 \frac{1}{2}$ in. finished, and those at the ends, $\mathbf{H}, 21 \frac{1}{2}$ in They are chamfered on the top edge to a line drawn $\frac{1}{4} \mathrm{in}$. from the inner edge and another $\frac{3}{4}$ in. from the top. The corners can be mitred, hut the better method is to dovetail them to form a frame, the top corners only being cut to a mitre, as in lig. 10 . In the latter case it is enough to glue them, but if simply mitred the wood must be bradcled, Before the plinth can be fitted to the carcass the proecting ends of the dovetails on the latter should be carefully sawn off a little away from the surface and then neatly planed down with a smoothing plane. but this must be left until a later stage. The plane should be used towards the centre of the sides and ends, as this will avoid breaking of the corners. The lid $J$ is planed down on the edges to the exact size of the top, 36 in . by 20 in ., and a moulding $2 \frac{1}{4} \mathrm{in}$. by $\frac{3}{4} \mathrm{in}$. prepared for the front

Tool Chest. Fig. 2. Sectional plan of tool chest shown in the opposite page. Figs. 3 and 4. Side and end elevations shown in section. Fig. 5. Sides of carcass joined by dovetailing. Fig. 日. One method of marking a dovetail joint. Fig. 7. Dovetail marier. Fig. 8. Alternative way of marking dovetail joint Fig. 8. Joint for securing bottom of chest. Fig. 10. Top corners of moulding cut to a mitre. Fig. 11. Bottom arranged with partitions. Fig. 12. Support for shelves. An explanation of all lettering will be found in the text
and ends as at K and L . This is dealt with in same width exactly, but the lengths are 33 in . the same way as the bottom plinth, with the and the total depth with the plywood bottom front corners dovetailed, but in addition to 2 in . The lowest shelves are $2 \frac{1}{2} \mathrm{in}$. deep and the moulding it will be necessary to screw on 32 in . in length. two battens M of 2 in . by $]_{\frac{1}{4}} \mathrm{in}$. wood, chamfered

The top trays should be provided with a plywood cover with $\frac{1}{2}$ in. by $\frac{1}{4}$ in. fillets on the inside edges for it to rest on, and holes drilled for

Tool Chest. Fig. 13. Plywood cover on top shelves of tool chest described in the previous pages. Fig. 14.
Sloping partitions. Fig. 15. Coinpartments for nails and screws. Fig. 16. Partition cross-halved. Fig. 17.

on one side and cut to 18 in . long. These are screwed on 1 in. away from the moulding and slightly tapered in front to allow the lid to fit down easily. The lid is hinged with $2 \frac{1}{2}$ in. by 1 in . brass butts let in flush, and should fit snugly on the top.

The next stage is to fit the partitions in the bottom. These can be made with $\frac{1}{2} \mathrm{in}$. wood, but $\frac{3}{4} \mathrm{in}$. is better. It will be seen in Fig. 11 that 4 compartments are arranged at the bottom; those at the back are divided into 3 parts, and the front one is a single one covered with a hinged lid. The actual dimensions do not matter very much. If the space is divided out equally it will be sufficient. It is suggested that the division pieces N and O should be about 5 in . wide; the partition pieces can be $5 \frac{1}{2}$ in. apart, and all let in $\frac{1}{1}$ in. deep grooves. This with $\frac{3}{2}$ in. wood will leave a $5 \frac{1}{2} \mathrm{in}$. space to be covered with the hinged lid P , measuring 30 in . by $6 \frac{1}{4} \mathrm{in}$.

## Details of Trays and Fitments

For the lid to clear the upper fitments, a 2 in. by $\frac{3}{} \mathrm{in}$. piece $Q$ is fitted at both ends. and a ledge or fillet R is screwed to the front for it to rest on; this should be $\frac{1}{2}$ in. square in section. Loose lids may be fitted over the open partitions, as shown by dotted lines, if desired, but they need not be more than $\frac{1}{4}$ in. plywood with $\frac{1}{2}$ in. fillets on back and ends. The shelf trays are arranged on supports T screwed to the ends of the case, and made from a 1 in . board, as in Fig. 12. The length is $17 \frac{1}{4} \mathrm{in}$., and it is built up with one $4 \frac{1}{2}$ in. wide piece rebated 2 in . down the side and $\frac{1}{2}$ in deep with a $\frac{13}{3} \mathrm{in}$. by $\frac{3}{4} \mathrm{in}$. piece screwed on underneath. Instead of rebating a 1 in . board, one 2 in . by $\frac{1}{2} \mathrm{in}$. and one $2 \frac{1}{2} \mathrm{in}$. by 1 in . piece can be fitted each side, the $1 \frac{3}{3} \mathrm{in}$. by $\frac{3}{4}$ in. strip being screwed to the latter piece. The top of this fitment is 3 in . down from the top of the case.
The two top trays are made with $1 \frac{1}{2}$ in. by $\frac{1}{2} \mathrm{in}$. wood, with long sides 34 in . long and ends 8 and $7 \frac{1}{4} \mathrm{in}$. respectively (Fig. 4). The corners can be nailed, but the shelves will be stronger and more workmanlike if dovetailed, and in this case the ends should be 1 in. longer than stated. The bottoms are nailed or screwed on, using $\frac{1}{4}$ in. plywood. The trays below are made in the same way; they are the
lifting up, as in Fig. 13. The trays can be partitioned off with strips of plywood to suit particular tools. One can be reserved for bits of all kinds, and have sloping partitions as in Fig. 14; another can be fitted to take the oilstone, bradawls, gimlets, rule, pincers etc,. The two top front shelves should be reserved for nails and screws, and partitioned off as suggested in Fig. 15. The partition pieces should be cross-halved where

Fig. 1
they join, as in Fig. 16, and are neater if they are housed into the sides, this being done before the tray is made up.
Ball feet or ball castors can be attached to the bottom, and handles fitted to the sides. A strong box lock fitted to the flap will keep the shelves secure, even if the chest should be overturned. The outside of the chest should be painted with 3 coats of good oil paint, removing the handles beforehand. The saws can be fitted to the inside of lid, as in Fig. 1; the method is to cut out shapes to fit the handles, screw them on, and fit a wooden turn-button. The tips of the saws should be fitted in slotted pieces glued and screwed on; these pieces are shown in Fig. 17. All the small tools, such as chisels, gouges, and other handled tools should
be placed in grooves in the bottom of the trays, as in Fig. 18, leaving the bottom partitions for the larger and heavier tools. A special part of the chest should be reserved for metal-working tools.

A tin of petroleum jelly should be kept in the chest so that all steel tools can be wiped over periodically. A place should be made for a tin of lubricating oil and a small oil can. If a paraffin blow lamp is used a special compartment will be needed for it, and a place to take a can of methylated spirits for priming the lamp. Soldering flux, kept in an earthenware bottle, will require accommodation also. If a petrol lamp is used it should be kept in a safe place out of doors, with the petrol supply ; paraffin blow-lamps are preferable.

TOOL CUPBOARD. It is often found convenient to arrange a small number of tools in a cupboard such as that illustrated in Fig. 1. The outside dimensions are 36 in. wide and high and 10 in . decp; the doors fit inside the framing and are stiffened with battens.
The internal arrangements allow of a 26 in . cross-cut saw on one door, attached to the shaped block at A; alongside is placed a tenon saw at 13 . The two racks on the other door, C and D , will take such tools as gange, square, pincers, screwdriver, hammer, gimlets, bradawls, ctc., suitable slots being cut to hold them sccurely. Inside the cupboard a jack plane will fit in the space at $E$, with the smoothing plane underneath at F ; a bow saw can be hung at the back on hooks at $G$, and on the other side can be hung a brace at H .

A mallet, oilstone, and rebate plane will rest on the to $\rho$ she!f at $J$; chisels and gouges can be placed in slots cut in a length of wood as at K, at the back of the lower shelf at L. . In front of the piece $K$, a flat length $M$ will hold the bits, and leave room in front for other tools. There are two pigeonholes at N and O for glass paper, etc., leaving the top drawer $P$ for small tools, and the lower ones, Q and R, for nails and screws. The advantage of this arrangement is that each tool has its own particular place and is easily picked out The whole collection can thus be placed in a convenient position.
The construction of the cupboard is quite simple. The outside boards are 1 in. thick finished, and should be obtained machineplaned to this size; two finished lengths of 36 in . and two of 34 in . should be prepared to a width of 10 in. The back is $\frac{3}{16} \mathrm{in}$. or $\frac{1}{4} \mathrm{in}$.

Tool Cuphoard. Fig. 1. Small cuphoard, shown open, for the handyman's tools. Fig. 2. Elevation of cuphoard when closed. Fig. 3. Side elevation. For lettering see text

 $\frac{1}{3}$ in., and end $15 \frac{3}{3}$ in. by $1 \frac{3}{4} \mathrm{in}$. by $\frac{1}{2} \mathrm{in}$., and a bottom $16 \frac{3}{4} \mathrm{in}$. by 8 in. by $\frac{2}{4} \mathrm{in}$., to fronts being rebated as for the drawer above. If flush handles are fitted the drawers can be full length from front to back, but if the handles project suitable allowance must be made in the lengths of the sides and the bottom. The inside of the drawers can be divided off to provide compartments for nails and screws, plywood being quite suitable for this purpose.

The doors are each 34 in . long and $\frac{3}{4} \mathrm{in}$. thick; one is $17 \frac{3}{8} \mathrm{in}$. wide and the other 17 in wide. A rebate $\frac{3}{8} \mathrm{in}$. each way is cut on the meeting edges of each door, as in the section at Fig. 8, and then a batten of 2 in . by $\frac{3}{2} \mathrm{in}$. wood is placed along the bottom of each door and glued and screwed on.

The fitments to hold the saws and other tools should be attached before plywood, and, although it can be nailed or betwcen $L$ and $V$ and be flush with the back of the doors are hung; the binges can be litted screwed on the back edges, a much neater job the narrowed portion of the shelf $L$, to provide at this stage but not screwed up. The saws is made if it is rebated, as shown in Fig. 3, a boxed portion for the chisel blades. The are fitted with a shaped block to fill in the which also shows the two sets of drawers.
The method of making the carcass is shown in Fig. 4. The sides $T$ are nailed or screwed to the top and bottom pieces U , but the various partition pieces should be housed into the outer frame first, as in Fig. 5. To do this work accurately, the wood must be marked out as far as possible with the parts placed together. The two sides T. should be placed side by side, a line being marked 1 in . down from each end to indicate the position of the top and bottom pieces U. A line is marked off 2 in. up from the bottom line, and this should be followed by drawer to fit in this space is shown in lig. 6 ; handle space, a turn-button made to the length, it is made with a front 27 in . by 5 in . by $\frac{3}{4} \mathrm{in}$., and then the pieces can be srewed on at the two sides $6 \frac{3}{4} \mathrm{in}$. by $4 \frac{3}{4} \mathrm{in}$. by $\frac{1}{2} \mathrm{in}$., and a back top. The tip of the saw should be arranged to 26 in . by $4 \frac{3}{4} \mathrm{in}$. by $\frac{1}{2} \mathrm{in}$. The front piece should fit just in the top of the bottom batten, but it be rebated $\frac{1}{2}$ in. each way at the ends, and will be necessary to make a slotted piece to $\frac{1}{2}$ in. by $\frac{1}{4}$ in. underneath to take the bottom, take the end of the tenon saw. The slotted measuring 27 in . by $6 \frac{3}{4}$ in by $\frac{1}{4} \mathrm{in}$. Glue, nail, piece in lig. 9 indicates the method of making or screw the parts together, and smooth with the supports for the tools on the other door ; glass paper to allow it to move freely in the each tool should be separately fitted, and the space. Suitable handles are fitted on the correct sized hole cut.
front as shown.
The various hooks are now placed in the
The two bottom drawers, Fig. 7, have fronts back to hold the bow saw and brace. A long $16 \frac{3}{3} \mathrm{in}$. by 2 in . by $\frac{3}{4} \mathrm{in}$., sides 8 in . by $1 \frac{3}{3} \mathrm{in}$. by strip of $1 \frac{3}{4} \mathrm{in}$. sq. wood is fitted to the back of another $\frac{1}{2}$ in. above, in order to give the position of the groove for the lower shelf V . The next shelf is 5 in . above, and two lincs are marked off. one 5 in., and the other $\frac{1}{2}$ in. above it. Thesc shelves, $I$. and $V$, measuring $34 \frac{1}{2} \mathrm{in}$. by $8 \frac{1}{4} \mathrm{in}$. by $\frac{1}{2}$ in., arc placed together so that the groove for upright W and its continuing piece underneath can be marked out, as well as a corresponding piece to the under piece on the other side between V and L . These pieces are 3 in . from the outside pieces, so that the grooves should be $3 \frac{1}{4} \mathrm{in}$. from the ends. The piece $W$ is $26 \frac{1}{2} \mathrm{in}$. by $8 \frac{1}{4} \mathrm{in}$. by $\frac{1}{2}$ in., and the 2 pieces $\%$ under the shelf $L$ are $5 \frac{1}{2} \mathrm{in}$. by $8 \frac{1}{4} \mathrm{in}$. by $\frac{1}{2} \mathrm{in}$. The piece at $X$ is 8 in . above the shelf $L$, and is cut to $3 \frac{1}{2}$ in. by $8 \frac{1}{4}$ in. by $\frac{1}{2}$ in.. the shelf $J$ is 31 in . by $8 \frac{1}{4} \mathrm{in}$. by $\frac{1}{2} \mathrm{in}$., and is the same height The division piece at Y is fitted half way between the sides, and cut to $2 \frac{1}{2}$ in. by $8 \frac{1}{4} \mathrm{in}$. by $\frac{1}{2} \mathrm{in}$. It will be seen from Fig. 5 that the long shelves which fit in the sides T are let in the full width, but the other parts are notched at the ends and fitted in stoplied grooves, $\frac{1}{i n}$. deep and $\frac{1}{2} \mathrm{in}$. wide. When all the parts shown in Fig. 4 have bcen prepared, and a 1 in. deep slot cut at the back of the shelf $L$, the carcass can be glued, nailed, or screwed together. In doing this, care should be taken to see that the corners are quite square.

The back is next cut to fit in the rebate. If, however, this method is not used, the width of the partition pieces should be 81 in. instead of $8 \frac{1}{4} \mathrm{in}$. Small brads or screws will be sufficient to retain the back in postion and make a solid case. A 27 in . by 5 in . by $\frac{1}{4} \mathrm{in}$. piece should be fitted in the space

Tool Cuphoard. A well-stocked tool cuphoard for the bome worker in wood and metal Courlesy of R Melhuish, Ltd.
the top sheif L, and slots as at Fig 9) cut in to take the chisels and gouges. These should be placed side by side as closely as possible : $\frac{1}{} \mathrm{in}$. in between the handles will be ample space. The slots are marked off on the strip and cut out. When fitted in position, the blades will fit in the space belween the top drawer and the back of the cupboard. A 1 in . by $\frac{3}{}$ in or lin. strip will be large enough to hold the bits, shanks downwards. The best method of making the holes for them is to drill a slightly smaller hole, and then cut square with a narrow chisel, as in lig. 10

Cupboard bolts are fitted, together with a lock, and then the outside can be either painted or sized, stained. and varnished. As the cupboard will be fairly heavy when completely filled with tools. special precautions should be taken to secure it to the wall. One method is to screw on strong brass mirror plates on the top and on the sides near the bottom, and screw to a wooden wall or to fibre plugs in a brick or plaster wall As an alternative, two mirror plates can be fitted at the top and the bottom supported with iron brackets.

## Tooth. See Teeth

TOOTYBACFE. There are two different diseased states of a tooth which may give rise to toothache. One results from in flammation in the soft centre or pulp of the tooth.

The pain in this form of toothache is sharp or shooting. It varies in intensity at different times: usually it is increased on lying down. But the tooth itself is not painful on being tapped. The taking of a meal tends to increase the pain, more especially if food is pressed into the cavity or hot liquids reach the exposed nerve.

In the treatment of this iorm of toothache it is most important to find the cavity in the tooth and, if possible, to clear away any food which may be causing pressure on the nerve. The next step is to fill the cavity with a small, loosely rolled pledget or wad of cotton wool dipped in oil of cloves or strong carbolic acid. The excess of these drugs should be gently pressed out of the cotton before insertion. The gum in the neighbourhood of the painful tooth may also le painted with tincture of iodine. After drying the gum with cotton, this should be applied with a small brush, and the mouth held open for 2 or 3 min ., so as to ensure that the iodine may not be washed quichly away. A dentist should be consulted at the earliest opportunity.

The other diseased condition of the tooth which may give rise to toothache requires different treatment. In this variety the pain is dull, continuous, and boring. The tooth is painful on pressure or tapping. The tooth frequently appears ulongated or raised in its socket, and when the teeth are closed it is often acutely painful. The inflammation in this case is really outside the tooth, round its root. From the inflamed stage it may pass on to suppuration, and the pain is then likely to be more or less continuous for two or three days, until the pent-up matter is able to force a passage through the bone, when a gumboil appears over the root of the offending tooth. The gumboil is itself painful to pressure, but the boring pain usually passes away almost suddenly with the appearance of the swelling.

Some relief may be got by painting the gum in the manner already described with a mixture of equal parts of tincture of iodine and tincture of aconite. Water, about as hot as it can be borne in the mouth, may also be tried. A saline purge is often useful in the carly stages of the disease, and 5 to 10 gr . of aspirin will frequently give relief in this form of toothache. All these remedies arc, however, quite unsatisfactory except for
temporary relicf, as the cause of the trouble remains. For this reason it is most important that the sufferer should have the offending root or tooth properly treated or extracted by a dentist. See Caries; Teeth.

TOOTH BRUSH. Handles that are fashioncd from bone are much the best for tooth brushes, as they do not easily chip or warp, and cut lengths of white French or unbleached yellow bristle are principally used for good tooth and palate brushes. The latter are made with larger handles and more rows of knots for cleaning dental plates, etc.
Substitutes are very little used in toothbrush making, although in very common varieties a tine libre horse-bair or poor bristle may be found. All quality brushes are made either by trepanning or are wire-drawn, the former being recognizable by the plugged holes in the end of the brush, and the latter by the lined back. The tops of the bristle are cut straight, concave, or serrated, the last style being preferred by many for thorough brushing.

It is cssential that a tootl) brush should be kept clean and dried after use. Washing the brush occasionally in warm water should not be neglected, as this will remove any accumulation round the roots of the knots A holder or rack should be found for tooth brushes where they can hang, or they should be stood up to drain and dry. On no account should they be left lying about, as they are liable to pick up undesirable matter. The importance of the operation a tooth brush is intended to perform warrants a more careful selection than is gentrally made. As in the case of all other brushes, cheapness is not only poor economy in the long run, but in use a poor tooth brush is decidedly unpleasant. Bristles break off or come out in the mouth and most of those remaining are entangled and cramped, with a few in a likely position to puncture the gunis when the brush is again used after being dried. A brush in this condition should always be discarded and a new one ohtaincd. See Dentifrice; Mouth wash; Teeth.
TOOTHPICK. Toothpicks may be cither of quill or of wood, being short pieces sharpened at one end. The latter are easily made with a penknife. The use of a toothpick, however, is not, in the opinion of the best anthoritics, advisable, as it is liable to injure the enamel. If there exists a cavity in the tooth in which food lorges, it is well to consult a dentist. See Teuth.

## Tooth Powder. See Dentifrice; Teeth.

TOPAZ. A semi-precious stone, the topaz is surpassed in hardness by very few other gems. It is found in several parts of Great Britain. Its value depends upon its depth of colouring, the sherry-coloured stones being considered the best. The white topaz is not unlike the diamond in appearance, but diamonds can always be distinguished by their excessive hardness, apart from their lustre. Pink topazes enjoy a certain measure of popularity, but their colour is artilicial, being produced by heating the sherrycoloured stones. There are also blue, green, orange, and pale and golden-yellow topazes.
TOP DRESSING: Of Plants. Rich soil or manure that is spread over the soil to assist the development of trees or plants is called a top dressing. It may be put on for the purpose of keeping the soil moist in hot, dry weather, or to increase the size of fruits or Howers. When such plants as chrysanthemums, lilies, or tomatoes are grown in pots it is usual to leave space at the top for a top dressing of rich soil when Hower buds or fruits are developing. Sand is an excellent nutumn top dressing for a lawn on heavy land; sifted
leaf-mould and decayed manure benefit a lawn on sandy soil.

TOPIARY. The art of clipping and training trees into various artificial and formal shapes is known as topiary. The yew is the

principal subject, but other trees and shrubs are frequently treated in this way, including box and holly. Many firms make a speciality of growing trees in tubs suitable for topiary work. Topiary trees should be clipped in May and again in August. See Box; Hedge; Yew.
TOPSIDE : Of Beef. The top or outer portion of the round of beef is known as the topside, the inner half bcing the silverside. It is a most economical joint for a family, especially where a large number are to be catered for ; but, although well flavoured and full of gravy when served hot, it is apt to eat dry when cold. It inakes excellent pie ineat, being full of gravy and free from bone or gristle. It is also good for stews, or a la mode beef, which requires lean meat.

Topside is often salted and boiled, but silverside is preferable for thie; purpose. The topside, however, is excellent if spiced for Christmas beef. A good-sized piece will take from a fortnight to 3 weeks to pickle. It eats better if it is larded with strips of fat hacon inserted in it at intervals. Portions of topside of beef may also lie potted; the meat should be freshly cooked, flavoured with vegetables and spice. It is better to stew it in the oven, adding as little water as possible. When cooked, the vegetables should be removed and the meat minced, then pouncled and potted in the usual way with butter, spice, a little of the gravy it was cooked in being strained and added. See Beef; Carving; Stew, etc.
Torch Lily. This is an alternative name for the red hot polier (q.v.).
TORENIA. This is a greculouse annual flowering plant, with violet-blue or yellow Howers. It should be grown in pots, or baskets suspended from the roof, containing a mixture of loam, leaf-mould, and sand. The secels should be sown in February in a temperature of 60 degrees. When large enough, the scedlings may be transferred to $5-\mathrm{in}$. pots, and the side shoots pinched off as they develop, in order to induce the plant to make bushy growth. The best species are T. Fourneri, violet-bluc, and T. Bailloni, yellow.
TORTOISE : In the Garden. A reptile with four feet and encased in a strong shell protection, the tortoise is cold-blooded and
lives to a great age. The two kinds usually liept in Great Britain are the land tortoise and the marsh tortoise or terrapin. The former is mainly herbivorous and can be fed on lettuce, cabbage, grass, dandelion and buttercup flowers, also soft fruits. The niarsh tortoise is mainly carnivorous.

If the land tortoise is to be kept in the garden it must be restricted in some way; or it will cause damage to vegetation. If possible, it should be assigned to a sunny position near a wall bounded with wooden boards, with a portion of the space covered with felt or Willesden canvas to provide protection from the sun and rain. Tortoises will bury themselves in the ground during the winter. They may be placed in a box containing soil or leaves, and left in a cool room until spring; when they awake they can be fed on lettuce or cabbage leaves, although they will eat very little at first.

TORTOISESHELL. Tortoiseshell, which is the horny covering of a species of sca turtle, varies in value, the finest shells being marked with reddish-brown and golden vellow shades. Many consider the blonde shells io be the most heautiful, but for brush-making the darker less transparent kinds are more popular.
Tortoiseshell is used to make all manner of toilet accessories. Manicure sets, powder boxes, hair brushes and combs, and complete dressing-table sets can be bought both in genuine and imitation tortoiseshell. Other articles made from tortoiseshell include spectacle rims, cigarctte, carcl, and match cascs, lorgnettes, purses, mirror backs and vanity cases. This shell is also used for inlaying clock cases, cabinets and other articles of furniture with delicate metal or brass tracery after the style of Buhl.
Whether tortoiscshell should be mounted or not is a matter of taste, some maintaining that it needs no adornment. Tortoiseshell may be cleaned with olive oil. See Buhl; Fan ; Spectacles.
TOUCH : The Game. Perhaps the simplest form of this popular outdoor children's game consists in one player running after the others with the object of touching one of them When he does this he must call out touch, and the one touched takes his place and becomes the chaser. A variant is known as touch wood. In this the players can sccure a respite from heing chased by touching anything of wood. As long as they do this they cannot he toucherl. A further variant requires the player who secks a respite to whistle in addition to touching a piece of wood. As sonn as he ceascs to whistle he can be touched.

TOURMALINE. The mineral that is known as tourmaline is found in a wide range of colours, but it does notrank anong the most cxpensive gems. Its tints include various shades of red, green, grey, blue, and yellow, the green tourmaline bearing some resemblance to the more valuable aquamarine.
Red tourmalines sometinues possess deep tints and are known as rubellites.

Towel. Bath towels ornamented with stitchery in colours. The upper has lines and stripes carried out in shades of blue and the lower has circles in mauve

Tourniquet. Improvised tourniquet applied to right brachial artery Lower bandage is applied to hold he stick used for twisting
easily made at home as they are simply formed by a straight strip of towelling 3 yd . long, or the most convenient length for the particular door on to which the roller is fitted. The strip is neatly seamed in order that it may revolve when required.

Bath towels are made of Turkish towelling in different qualities and sizes. The largest are known as hath sheets and are usually stocked in two sizes, 48 in . by 72 in ., and 48 in . by 80 in . Other white Turkish towels vary in sizes from about 20 in . by 40 in . to 30 in . by 60 in . These towels are sold hemmed ready for use. Terry towelling which is obtainable in colours and also in patterned designs is used to make coloured bath towels Coarser bath towels are light brown in colour, but are strong and hard-wearing.

Hand towels vary greatly in quality and price, and are made in 3 usual sizes. 18 in. by $32 \mathrm{in} ., 20 \mathrm{in}$. by 36 in ., and $22 \mathrm{in}$. by 40 in. Huckaback towels in fine weaves with damask borders finished by hemstitching are always pleasing. For family use a somewhat stronger weare is recommended and plain hemming may be considered more satisfactory than hemstitching. Huckaback towels may also be purchased with coloured borders, and coloured damask guest towels are obtainable. The usual size for these is 15 in . by 22 in .

Ornamental Towels. Bath, hand and guest towels may be improved by worked monograms or borders in coloured cross-stitch. A pretty design of a type suitable for the latter purpose is slown in page 420. Guest towels can be made of fine white huckaback, measuring 15 in . by 22 in. after being hemstitched. Embroidery is usually placed only at one end, but both ends are hemstitched. Very dainty trimming is supplied by a small design in Renaissance or Khetha work, both of which are illustrated in page 420. The embroidery can be worked in colour, or in white on a coloured towel. Crochet lace is also a suitable edging and trimming.

Many women buy plain towels of a good quality and decorate them with a little stitchery. The towels here illustrated arc embroidered in coloured stranded cottons. The top one has 3 lines and the row of short vertical stripes worked in chain-stitch in 3 shades of blue. The lower one has 3 lines of stem-stitch and a row of circles worked in plain and raised satin-stitch, using several shades of manve. Other borders may be carricd out with sprigs of Howers in lazy-daisy stitch, buttonhole rings and snail-stitch. Three rows of different feather-stitching is also an effective trimming. 1 Roller towels and the coarser bath towels may be marked with marking ink, but bath towels of good quality are improved by initials boldly designed or embroidered monograms.

Towel Airers and Rails. A towel horse to match the wood of each washstand is usually provided, when there is general bathroom accommodation for a number of bedrooms. A towel airer is a convenience in the bathroom It is often made in the form of a plated stand either heated by electricity or by connexion with the hot-water system. Aluminium towel rails arc obtainable in lengths varying from 24 in . to 26 in . with wall brackets for fixing. Swing towel airers in the same metal are marle with 2 or 3 arms. Burnished aluminium is labour-saving, rustless, untarnishable and incxpensive. See Linen.

## Toys and Toy Making

## Suggestions that will Interest both Parent and Child

The important part played by toys in child life is recognized in this article, which adds to the information given under the headinps of individual toys, such as Aeroplane; Doll; Kite; Knitted and Stuffed Toys; Jigsaw Puzzle; Noah's Ark, and various model engineering contributions, such as Boat; Engine; Locomotive; Railways. See also Casting; Child; Christmas; Nursery
Children find expression in toys from earliest cost but by the amount of interest and amuseinfancy. A rattle or a coral with tinkling bells ment that they can get out of the toy inspires them with the desire to repeat the pleasant sound. A brilliantly coloured hall excites their admiration. They pass through a stage of surprise at a jack-in-the-box or clockwork animal to curiosity, which, though perhaps indulged in at the expense of the particular toy, is the beginning of knowledge and invention. Imagination is stimulated by the games of make-believe, from a Noah's ark or doll's house to the wonder of things made by hand out of toy looms, from carpentering sets and plasticine to a meccano set.

The playing of games of skill with hard and fast rules develops a child's character by the discipline of competition within limits, but into his play with toys he weaves the fancies which are the outcome of his individuality.

For this reason it is a mistake to interfere too much with his choice among his toys. Having had the winding-up of a new tumbling clown explained to him, he may be delighted with its novelty for a while, but when that has worn off hic has no further use for it, and turns to play for hours with a grocer's shop, weighing out commodities from bottles and tins on miniature scales, or doing up tiny parcels and falling in gladly with a suggestion that his horse and cart should be a delivery van. The great thing is that he should learn concentration by being absorbed in whatever he is doing at the time. Boredom lies in going from one toy to another in a desultory fashion

Toys should be put away when playtime is over, and a child should have a special shelf if a cupboard or locker of his own is not possible. If it can be avoided, it is a mistake ruthlessly to sweep away his unfinished creation of bricks or the setting of a farmyard drama, but a warning can be given that time is nearly up, and sometimes a little assistance will help towards the satisfactory completion of an edifice or episode. The care and repair of toys should be taught to children from an early age.

Nearly everyone who has had to do with young children has had the experience of seeing an expensive toy fail to please or be cast aside in favour of a cheap one. Value is re presented to their minds not by its

The younger the child the more eager he is for a toy which is symbolical rather than real. istic. The round block of wood spotted red and blue, with roughly carved neck and head edged with fur, and set on four legs and a green wheeled stand, is more dearly loved than the finest mode! of a pony with real skin and hair. They outgrow this stage when a Noah's ark becomes silly because the elephant is out of all proportion to the rabbit; or the nursery floor as an ocean for the ship on wheels fails to satisfy the little boy who has seen a friend launch his boat on real water.

Some children delight in miniature things. They like to collect families of tiny dolls, furniture, and animals. A few low shelves where they can set out these things and leave them undisturbed till the next playtime is a happy arrangement, especially if provided with a curtain on rod and rings. Other children like to impersonate the characters in their games. A toy outfit of a bus conductor may give more pleasure than a mechanical model of a motor bus, even though a sofa with a few dolls on it represents the vehicle to be driven.

Outdoor toys are nearly always fascinating. Hoops, skipping-ropes, scooters, battledore and shuttlecock, sailing boats, balls, and dolls' perambulators all have their attractions, but probably none give more joy than the wooden spade, the shrimping net, and the tin pail at the seaside. The garden becomes an absorbing toy. Such gifts as a practical toy gardening set, consisting of a number of tools and a wheel-barrow, and a small piecc of the garden, usually have a great appeal.

When choosing a toy as a present, especially for a small child, occasionally people makc the mistake of giving something which amuses them, such as a mascot or novelty of the moment, which has no meaning to the little recipient, instead of some simple toy which would really pleasc. Should the present be intended to impress the parents of the child

\& glued in hole bored across Axletree to give further security to the Ax/e screw

Toy. Fig. 1. Diagram illustrating methods of repair. A. Detail of lug and slot for wheels of mechanical toys. B. How to solder lugs in body construction. C. rather than the child himsclf, it is better to let it take some other form

Mechanical Toys. Constructional toys in the form of collections of parts afford much entertainment to children of the age to understand them. It is a waste of money to give such sets to a younger child, who will be better pleased with a robust clockwork toy. The constructional set depends for much of its entertainment and educational value upon the appeal it makes to the imagination and ingenuity of the owner, who can combine and re-combine the parts in a variety of ways. The parent can initiate the work, and assist, but the youngster should be left to solve his own problems as far as possible. Steam engines and clockwork or electric motors can be purchased to supply power to the working models thus built up.

Model railways are dealt with in a separate article, but a word or two here about toy train sets may be appropriate. The common tinplate track as supplied with train sets is usually neither strong nor durable, and it is well worth while to purchase a good set of rails from one of the reliable firms which specialize in these goods.

A word of advice may be given here about clectric sets. An accumulator is the best means of supplying the current to the conductor rails. It can be placed on a shelf out of harm's way, the leads being talsen down to floor level and ending in a plug fastened to the skirting. The leads should be secured to the wall in some way, and also to the shelf, so that the battery cannot be dislodged by a pull on the wires. Another method is to make a simple wooden box to hold the accumu lator, the lid being secured by a small lock, and the box being screwed to the floor in a corncr of the room In this case also the leads can be taken to a plug on floor or skirting. Train scts can be oblained for connecting to the electric light mains, but these are not suitable for children without supervision.

There is a third method of running an electric train, in which a small battery carried in the engine or tender supplies the current. The battery has to be replaced by a new one at frequent intervals, of course. but this is a simple method, and no conductor rails arc needed on the track. The above remarks apply to the smaller or toy train sets.

Mending Toys. The cheaper clockwork toys do not usually admit of repair, and even in the case of the better made ones the gears and spring wear out or lose resilience, as the case may be, after a period of strenuous service.

In repairing mechanical toys made of metal, a certain amount of skill with the soldering iron will reduce labour considerably. Where toys are finished by a lithographic printing process, it is absolutely necessary to remove the coating of paint entirely, and to get down to the bare metal by scraping, before attempt ing to apply the solder. Many cheap toys are made with cog wheels fitted to their shafts or axles with lugs or slots, or by flattening the spindle each side of the fly-wheel boss. Such devices usually give trouble, and even a new toy will be considerably improved in strength and its life trebled by soldering such joints together. If the paint has to be scraped off to do the soldering, the part can be touched up afterwards with a little oil colour. Points in body construction can also be dealt with in a similar manner, the soldering of the lugs being effected from the inside wherever possible.

Glue is the proper adhesive for wooden toys, but in addition it is often advisable to drill a hole and insert a wood screw across the joint of a fractured part. In fitting screws the preliminary drilling for the sceew should not be forgotten, as toys are generally made of the cheapest kind of wood.
The toy maker frequently drives a big nail or screw into the end of a wooden rail and

Toy. Fig. 2. Flufly rabbit which is very realistic when made in white fur cloth
makes the nail the axle of a wheel supporting the whole weight of the toy. Such fixings in end grains are never satisfactory. A cure may be effected by crossing the screw with a wooden plug, as illustrated, or by fitting an all-metal axle such as is used in a perambulator: Wooden wheels should be bushed with short pieces of brass tube. The methods of repair mentioned are illustrated in the accompanying diagram (Fig. 1).

Soft Toys. Instructions are given in the article on Dolls for making a rag doll, and other soft toys are dealt with in the article on Knitted Toys. Plush or fur cloth covered toys are easily made by the home worker.

An odd length of white fur cloth can be utilized for the rabbit shown in Fig. 2. The main part of the body and the head are cut in one, but the underpart and the ears are added separately. A quarter of a yard of cloth, 48 in. wide, is needed, together with a little pink flannelette for lining the ears.

When cutting out, use the cloth folded with the selvedges together, and arrange the patterns, cut to the shape shown in Fig. 3, in the positions there seen. First join the long, straight seam of the base or underpart ; then take it, still folded, so that the seam runs along the top, but with the wrong side inside, and slip it between the two layers of the main body. The latter should be so put together that the right sides face.

Stitch the cdges of each layer of the base to the edges of each layer of the main part, matching the sets of two notches, and also drawing the curved back part of the base down to the lower edge of the main part. Next stitch the two main parts of the body together above the inserted base portions, commencing at the front just below the head, and working around this and along the top of the body to the back of the inserted base

Leave a small opening in ime part of this seam, however, so that the stuffing may be

put in. Turn the shape inside out, stuff it tightly with kapok, and then sew up the open. ing. Line cach ear with the flannelette; then make a pleat in the straight edge and sew it to the head. The addition of two boot buttons for the eyes gives the finishing touch.
Patterns for other toys of this description can be obtained from "Best Way" 291a, Oxford Street, London, W.1. A delightful example, called Tinker Boy, is illustrated in Fig. 4. This curious

stand should be made, as the toy will act equally well on the edge of a table or mantelshelf provided the balancing wire is long enough. Another form of balancing toy is shown at Fig. (i, string being substituted for the wire to hold the weight, and the various parts

Toy. Fig. 3. Diagrams ior making the fluffy rabbit, showing the shapes for ear, base and body, and (above) how to join up the cover before stuffing creature requires 1 yd. woollen plush, 2 glass of the body hinged together. It is advisable eyes, bell and ribbon for the neck, a little to use a close-grained wood or 3 -ply, the black darning wool, and kapok for stuffing. thickness of each piece being $\frac{3}{16}$ in The The latest "Best Way" book on Home-made various parts are shown in Fig. 7, and are cut Toys should be obtained at a ncwsagent's, as out with a fretsaw ; the two pieces for the new patterns are irequently invented and body should be pasted together temporarily described.
Wooden Toys. Toys can be made by the home craftsman from wood with a few simple tools. with a piece of paper between and sawn to shape, as this ensures their being alike. Al! edges and surfaces should be glasspapered. To begin with balancing toys, there is The small pieces are glued to one of the considerable scope body pieces in the positions indicated by the for inventiveness dotted lines. Small nails are driven into the with eitherthe fixed ends of the head and tail picces, which should or flexible balance. be further rubbed with glass paper to make A good example of them a little thinner than the small pieces this kind of toy is attached to one of the body pieces. Holes are shown in Fig. 5, in bored or drilled through the body and the the form of the bal- head and tail for the hinge screws, and ancing horse. The slightly enlarged in the two latter pieces to outline of the horse, allow free movement. The balance weight or anyotheranimal, can be of the same shape as that used for the horse, but it should have a groove or a hole through it to enable the string to be fastened. A round ball can be cast in the same way, and looks neater than the flat weight.

Each length of string should be about 8 in.. but the
is marked out on a piece of thin wood about $\frac{1}{3}$ in. thick and cut out with a fretsaw. Any closegrained hardwood is suitable for the work, but with plywood there is little risk of breakage. The pendulum or balance should be of lead, which is cast in a plaster of Paris mould or in a well-greased tin lid. The wire is placed in the mould before the lead is poured in, and the other end of the wire is pressed into a prepared hole in the body or other suitable position on the animal. The stand is made from short lengths longer it is the better, as the toy will work of dowel fitted in a wooden base; the uprights for a longer period. It is necessary to support can be square in section provided sufficient the stand either by a weight at the back or space is allowed for the balance wire to a small $G$ cramp. The toy can be made move freely. It is not essential that the more realistic by fitting it on a platform
and making a small food trough undor the small end. undercutting it $\frac{1}{2}$ in. head A development of this kind of toy is The dovetail to fit in the slot made by arranging two parrots on a strip of in the axle block should be wood and connecting the strings to a pendu- sawn out and the piece glued lum, or cutting the shape of two men holding a hammer and striking an anvil, which is arranged between them.
The pole cart in Fig. 8 is composed of two sides nailed to end pieces and to a base. Cast-iron whee!s are screwed to axle blocks, and the handle, which is fitted to a projection in front, is so arranged that it will not fall down further than an angle of $30^{\circ}$ in front. The two sides are 16 in by $6 \frac{1}{2}$ in by $\frac{1}{2}$ in.. the ends 9 in by 7 in by $\frac{1}{3}$ in, and the bottom 20 in by $10 \frac{1}{2}$ in by $\frac{1}{2} \mathrm{in}$, planed up and finished smooth, preferably from a liardwood such, for example, as birch or elm

The sides of the cart should be securely nailed or screwed to the ends and the bottom attached in the same way. The axle blocks are 12 in by $2 \frac{1}{8}$ in by 3 in and must be of hardwood. One side is quite straight, and the other shaped to 1 in deep at the ends from a line drawn 3 in each side of the centre, and the ends cut off with a chisel to an octagonal form.

One of the axle blocks is screwed to the bottom board 1$\}$ in from the end: the other, as in Fig. 9, is slotted to take the dovetailed end of the projection to carry the handle. Plane up a length of hardwood to 11 in by $4 \frac{1}{2} \mathrm{in}$. by $\frac{3}{4}$ in., reduce the end to 24 in. wide, and cut a 24 in. long by $\frac{3}{4}$ in. alot at the

Fig. 15. Push horse shown in side elevation, with dimensions. Fig. 16. End elevation of the push horse
The winding roller is cut to 3 in . from a length The winding roller is cut to 3 in . from a length
of 1 in or 1 l in round, axles being provided by suitable lengths of hard brass wire fitting through holes bored in the sides of the uprights. The latter pieces are nailed to the base with a 3 in . by 1 in . by $\frac{1}{2} \mathrm{in}$. piece, and a 4 in . length of $\frac{3}{8} \mathrm{in}$. dowel between at the end to strengthen the base, as shown.

The uprights to support the base of the arm or jib are $2 \frac{1}{2} \mathrm{in}$. by $1 \frac{3}{4} \mathrm{in}$. by $\frac{1}{2}$ in. ; they are tenoned at the ends, fitted into slots in the base, and the top corners trimmed off. The slots or mortises in the base are '" in from the ond and $\frac{3}{4}$ in. apart; the arm is made from two pieces 15 in . by $\frac{1}{8} \mathrm{in}$. and tapered evenly from $1 \frac{3}{4}$ in. to $\frac{3}{\frac{3}{2}} \mathrm{in}$. Two $\frac{1}{2}$ in. thick blocks are prepared for fitting between the lengths.

They must be shaped to allow of a width of $1 \frac{1}{2} \mathrm{in}$. at the bottom and sufficient to take a small grooved pulley at the top. The ratchet wheel and catch in Fig. 12 are made from a piece of sheet brass. The method of flattening the ends of the wire for the axle, together with the handle, is shown in Fig. 13. The arm is held in position with suitable lengths of small brass chain, and similar material can be used for the rope, a hook being fitted on the end.
The travelling crane in lig. 14 is shown in a small size, but if the main proportions are retained it can be built much larger. The number of parts have been reduced as low as possible, and the construction could hardly be be more simple.

Dimensions for a push horse are given in the elevations in Figs. 15 and 16 , and represent a medium size. The body is cut to 10 in. from a round of 4 in . diameter, and Hattened at the bottom; the legs are 10 in . by 1 in . diameter, tapering to $\mathcal{F}$ in. at each end. The head is shaped from a piece of $5 \frac{1}{2} \mathrm{in}$. by $4 \frac{3}{\mathrm{in}}$. by $\frac{1}{2} \mathrm{in}$., and let in to a depth of $\frac{1}{2} \mathrm{in}$. The base is 12 in . by 4 in . by $\frac{1}{2} \mathrm{in}$., with 1 in . square lengths underneath to screw the wheels to, tho latter being $2 f$ in diameter and $\frac{3}{4}$ in. thick if of wood, as is usual.
The handle is formed with two 18 in . by $1 \mathrm{in}$. by $\frac{3}{8} \mathrm{in}$. lengths, with a 4 in. length of $1 \frac{1}{8} \mathrm{in}$. diameter round between, these pieces being joined together with $1 \frac{1}{2} \mathrm{in}$. wire nails. The saddle and harness is usually formed with
coloured paper, such as the imitation morocco paper used by bookbinders. The mane and tail can be made from a piece of an old skin rug. By fitting a projecting blook to the front axle a pole can be fitted, in the same way as for the pole cart, that will enable the horse to be pulled instead of pushed.

TOY DOG. This name is given to various small dogs which are sufficiently diminutive to be carried on the arm of their mistresses. They are obtainable in many breeds, the Pekinese being one of the most $\mu$ ppular, while Pomeranians and Yorkshire terriers are also much sought after.

The original toy terrier, which was only sobtainable as a toy dog, is not so often seen Aince breeders took to breeding smal! dogs of other and more attractive types. The Belgian griffon is another favourite, while the King Charles was perhaps the first of all, and still maintains its popularity to a great extent. With Yorkshires, Pomeranians, pugs, and the like, it must be specially mentioned if a toy size is required, as they are also bred to their normal sizes. See Dog; Japanese Spaniel : Pckinese; Pug.

T PLATE. Steel or iron plates in shape resembling the letter T are sometimes employed to strengthen the joints of woodwork. They are arranged in pairs, one on either side of the joint, and bolted right through the timbers, holes being provided in the wood and the plates for this purpose. T plates are also placed on the tie-beam and the vertical posts of a queen-post truss.
TRACHELOSPERMUM. This is an evergreen climbing shrub for greenhouse cultivation, sometimes known as Chinese jasmine or Chinese ivy. The best species is jasminoides, which produces fragrant white blossoms from June to August and reaches a height of 12 ft . It should be planted in spring, in pots of fibrous loam, peat, and sand, or in well-drained borders, training its twining growth to trellis or walle. The plant should be pruned slightly after flowering.
Tracing : On Paper. The operation of tranaferring a drawing or picture by means of prepared paper can be done in two ways. A sheet of tracing paper, which is a specially prepared semi-transparent paper, is placed on the drawing, and the lines underneath are drawn over with a pencil. This method of providing a duplicate of a prepared drawing is used by architects and builders as well as woodworkers and engineers, but tracing cloth is often employed instead of the paper, as it is not so easily torn. Duplicate plans and elevations can be made in this way, colouring being done with coloured inks or water colours.
Anothe: method of transferring drawings is to trace them through a sheet of carbon paper placed underneath the drawing. This method is useful for transferring designs on to metal wood, and other materials.

In all tracing it is necessary to keep exactly to the original lines; at the same time it gives the skilled draughtsman an opportunity of correcting faulty lines on the original. In using carbon paper, it is advisable to pin the dvawing at the top so that the progress of the work can be followed, otherwiso it may be found on the completion of the work that important details have been omitted. See Drawing; Embroidery; Plan.
TRADESCANTLA. This is the name of a genus of hardy herbaceous and greenhouse plants. The favourite hardy kind is the Virginian spiderwort (virginiana), 2 ft . high, which bears purplisb-blue flowers in summer and will thrive in ordinary soil in a shady border. It is known as Flower of a Day, because the individual blooms soon fade, but the plants flower throughout many weeks. The greenhouse species are valuable trailing

Tradeacantia. Trailing foliage of a greenhouse
plants which will flourish in soil beneath the greenhouse staging, or if grown in pots they form an attractive edging. They may also be planted in hanging baskets. A compost of loam, leaf-mould and sand suits them and they are very easily increased by cuttings.

TRAGACANTH. This describes a gummy exudate from a Syrian tree, which has the property of swelling into a gelatinous mass when added to cold water, and has a soothing and demulcent action when applied to irritated mucous surfaces. It is an ingredient of some throat lotions, but its chief use is as a means of holding in suspension iusoluble powders, resins, and oils.

TRAINING: Of Plants. During the first few years of growth the training of fruit trees is of paramount importance. The nursery specialist supplies young trees in various shapes, chiefly bushes, pyramids, standards, cordons, espaliers, and fans.
Bush Trees. Bush trees are the best allround kinds for the amateur. They are easily accommodated to limited space if kept properly trained, and are particularly suitable for simple cultivation and the production of such utility crops as apples, pears, plums, gooseberries, and red, white, or black curiante. Yenrling maidens of apples, pears, and plums usually consist of one main stem which is shortened during winter to about six buds. The following season these buds will produce leader and side shoots, all of which will require shortening to about onefourth their length. During their third season they will develop further, leading and lateral growths, one of which should be pernsitted to grow

Training of trees and plants. 1. Method for frames: $a$, cane or wire anpports. 2. Eapalicr for fruit : $a$, wood ; $b$, canes ; $c$, wire. 3. Greenhouse trainers a, rings, ringed ataples and wire. 4. Garden trainer for weeping roses or climberg: $a$. child's hoop; $D$, cross strainers ; $c$, wire : $d$, wooden support with tarred base and holed apex. 5 . Garden trainer of wood and netting for sweet peas
base and holed apex. $a$, tarred bases for insertion in soil
at the extremities of each branch, a! laterals being reduced to their fourth leaf.

Gooseberries and red and white curranta can be raised from simple cuttings, denuding each of all its buds except the three top ones. These will produce threc shoots, all being allowed to continue growth until the fall of the vear, when they are cut back ahout half-way. Thus, the following season a larger number of shoots will progress, these in turn being reduced in !ength rluring the winter. The next year they will require summer pruning of all laterals, with another slight trimming during winter. In preparing cuttings of black currant none of the buds must be taken off.

Pyramids. Pyranids are suitable for apples, pears, plums, and cherries, and are trained by cutting back a maiden tree to about 12 in . from its stock as a result of which leader and side shoots will appear. During winter the leader should be rerluced by about ove-third and laterals by half, staking the former securely to keep it upright. Subsequent training is similar to that for bushes, but particular care must be taken to ensure pyramidal shape.

Standard Trees. These have a clear stem of about 6 ft . and a head of branches which develops from the uppermost buds. Every winter for the first few years the season's main shoots should be cut back by about half to ensure a foundation of strong branches. Care must be taken to keep them about 2 ft . apart to prevent overcrowding in subscquent years. Side shoots should be pruned to two or three buds each winter for the first few years, but established trees are pruned chiefly by thinning out superfluous shoots and branches. Half standards, which are on stems about 4 ft . high, are treated in the same way.

Cordons. Single cordons are trained from a maiden stem and cut back about half-way during winter. The resultant leading shoot is then permitted to grow on, all side growths being carefully reduced to two buds in winter. This procedure is continued until the stem is well furnished with fruiting spurs.

Double cordons are trained by allowing two shoots to grow on after the first proning back of the maiden stem. Another form of cordon is horizontally trained, its two cordons being trained to strong horizontal wires about a foot or so from the ground, to which point the primary cutting back of stem is carried. Apples, pears, red and white currants, and gooseberries all do excellently in cordon form.

Espaliers. Espalier is a term given to the method of training fruit trees on supports of
iron, stout wire, or wood, as usctul and decorative margins to walks of kitchen garclens, trees thus trained heing known as espalier trees. Such trees are almost beyond the average amateur and therefore should be obtained reads formed from a truit specialist. Treatment subsequent to planting is merely training to supporte and suitable pruning to maintain and increase fruiting spurs.

Fan-trained trees, also, are best sccured from the specialist. This type is suitable for the cultivation of apples, pears, plums, peaches, figs, and cherries on walls. See Wall.

The Diagram Explained The diagram shows also methods of training adaptable to roses of a weeping character, and also to greenhouse and outdoor plants. Fig. 1 shows a simple fixture for frame culture of cucumbers. tomatocs and plants of similar habit. It consists of a simple stem support, with a top, length of canc or stretched wire from front to back of frame. Fig. 3 gives at a glance an excellent wiring method of training plants in a lean-to greenhouse, the principles of which may easily be extended to the full-span or any other type of house.

Fig. 4 is an umbrella trainer of particular value for the display of standard weeping roses or other drooping plants, its simple components being merely a child's hoop, an upright with cross picces, and a suflicient quantity of stout wire : its conslruction is quite easy to follow from the sketch. Fig. 5 is another simple but useful type of trainer, specially suitable for sweet peas, but handy also for climbing nasturtiunis and p!ants of similar habit. It may be constructed of two circular pieces of wood-butter-tub hoops will do quite well, these being attached to four fairly stout uprights as sketched. The bottom ends of the uprights should be tarred or creosoted to prevent decay. Wire, or preferably rot-proof string, is then arranged, tubular fashion, securely to hoops and uprights, thus forming an inexpensive contrivance. This is particularly effective for swect peas when grown in tubs. The netting employed should have a good open mesh.

TRANSFER. Designs printed on thin, transparent paper and capable of being transferred to other surfaces are known as transfers. They can be bought from most fancy necdlework shops and artist's colourmen and are obtainable in llower, fruit, and other designs. They are used for embroidery, beadwork. painting on glass and textile fabrics, pattern printing, leather work, gesso and liarbola work, batik, and for transferring designs on to lampshades.

To use a transfer on a textile fabric, place the latter on an ironing table with the right side upward, then pin the transfer to it with the waxed side down, and press with a moderately hot iron. If the material is thin, the flat of the iron should not be used, otherwise the wax may spread and cause distiguring marlis. The heel of the iron may, however, be used without harmful results. When painting on transparent materials such as gaure or fine georgette, the design mav be tacked underneath the fabric, or the latter may be pinned over the transfer on to a board.

Transfers can be used scveral times, even though the wax has been ironed off, for the outline still remains. They are also used in the following manner for transferring to paper, parchment and prepared wood surfaces: Cover the portion of the fabric to which the design is to be transferred with a sheet of carbon paper, lay the transfer on top, and pencil over all the lines.

Various women's periodicals specialize in transfers for embroidery and designs which may be adapted for other art crafts.

Transfer for Applying Decoration. Another kind of transfer is specially prepared for applying decoration to various materials in

the form of lines. coloured designs, and pictures. Imitations of painted decoration, marquctry work, bandings, stringing, sign wriling, glaining, Iloral patterns, and pictures in miniature can be obtained in the form of translers.

In applying transfers to wood, the surface must be perfectly smooth and clean, and preferab!y borlied up, with french polish. although this is not essential. The exact position of the transfer must be marked lightly, the outlines of the design being indicated on the back of the transfer, so that it is not difficult to place the paper in the correct position. First cut away most of the unnecessary paper surrounding the edges of the transfer, leaving a margin of about $\frac{1}{8} \mathrm{in}$.
The face of the transfer is wiped over with a clean duster, and then with a small, stiff brush it is given a thin coat of gold sizc. The paper is then placed on one side, frce from clust, for the size to dry. A suitable size can be made by dissolving $\stackrel{1}{2}$ oz. of best gelatine in 1 pint of water. If the wood has been bodied up, the surface should be rubbed down with powdered pumice-stone placed in a pounce bag and linally wiped over with a clean, dry rag.
The transfer is ready for application when the gold size is tacky. On no account must the surface be wet. It can be tested by placing the end of the finger on it. If the finger sticks without pressure the surface is not dry enough, but if a little pressure is needed to make it stick to the linger it is ready for application. If the transfer is on duplex paper, it should be divided and the thick backing paper thrown away. The surface of the transfer is carcfully placed in position and well rubbed into contact with the work. It should be noted that when once the transfer has been placed on the wood

Transfer applied to wood in imitation
it cannot be shifted without spoiling it. It is therefore best to commence with one corner and gradually press it into contact . this method also minimizes the chance of air bubbles appearing under the transfer when finished.

Immediatcly the transfer lias been pressed well down on the surface, rub it further into contact with a slightly damp spongc. The sponge is dipped in warm water to wet it thoroughly, and the paper surface of the transfer is wetted, allowing about 5 min. for the water to soak in. One corner is lifted up and the paper is peeled off, leaving the design on the wood. The coloured surface is lightly washed over with the wet sponge, working from the centre to the outsides, and it is then dried by gentle pressure with a clean cotton rag. If there are air bubbles, they may be removed by pricking with a needle point and pressing the transfer down with a wet finger tip.
On no account should the transfer at this stage be touched with a dry finger, as the paint will stick to it and spoil the work. The superfluous gold size round the edge of the transf('r can be removed by dipping a dry sponge in turpentine and wiping over the transfer from the centre to the outside until all traces have disappeared. This operation should not takc more than a few seconds or the turpentine will attack the paint and dissolve it. Directly the size has been removed, the surface should be wiped dry with a clean cotton rag. When dry the colour will harden, and can be coated, if desired, with a transparent polish.
The method of applying coloured transfers or linings to polished metal surfaces is somewhat similar, but special care will be necded to fit the paper on curved surfaces, otherwise the finished work will appear slovenly. In transfers of lines making a panel with ends, these portions should be applicd first and then joined up with butt and not overlapping joints. To make an effective join, the length of line between the cnd portions must be accurately measured, and, in the case of the end picces as well as the lines, as much of the outside paper as possible cut off. See Embroidery ; Graining; Painting on Textile Fabrics.
TRANSFORMER: In Wireless. This is an apparatus for converting an alternating current from one voltage to another and more convelicnt voltage. It comprises two windings, viz. primary and secondary, which are coupled to each other so that energy is transferred from the primary to the secondary by electromagnetic induction.

In low-frequency alternating current circuits the windings are mounted upon a laminated corc of a metal having a high magnetic permeability, such as iron or an alloy in which iron is the main constituent. In high-frequency transformers, the primary and secondary windings are wound upon an insulated former and a core is not used.
When the primary winding of a transformer
is connected to a source of alternating current supply, a magnetic flux is set up which becomes linked with both windings, the voltage per turn being the sanic in each winding (neglecting losses). The voltage across the secondary winding is, therefore, directly proportional to the ratio of the number of turns on the secondary to the number of turns on the primary. Thus, if the ratio of secondary to primary turns is three to one, the voltage across the secondary terminals will be thrce times the voltage across the primary terminals.
In a perfect transformer the secondary power output will be the same as the power or energy consumed by the primary, but in practice the power factor and losses in the windings and core have to be taken into consideration. Transformers may be designed to give a high secondary voltage and a correspondingly small current. or a low voltage and a large current.
Transformer Coupling. This is a method of coupling wireless receiving valves in cascade for a mplifying at high or low frequency. In a high-frequency transformer the secondary is usually tuned and the primary is untuned, the number of turns on this winding being adjusted to give the required degree of selectivity. The coupling between the two windings is normally fixed, and the degree of selectivity will be minimum when the transformer has a turns ratio of $1: 1$. Decreasing the number of turns on the primary increases the selectivity but may decrease the energy transfer between the primary and secondary circuits, and therefore the sensitivity. In practice it is necessary to effect a compromise with the object of achieving good sensitivity and adcquate selectivity.
Transformer coupling is employed in lowfrequency magnifiers, and provides greater magnification per stage than either resistancecapacity or choke coupling. A good lowfrequency transformer should possess a high primary inductance and a secondary winding of low self-capacity.
A high primary inductance ensures an adequate amplitication of the low notes, but it is essential that the valve connected in the primary circuit should have an appropriate A.C. resistance or impedance. Suitable types of valves are usually recommended by the makers of the transformers and these should be employed. The high-tension voltage nust be adjusted so that the current flowing through the primary winding is within the linits specified for that particular transformer.

Transformers having alloy cores are often isolated from the high-tension current flowing in the anode circuit of the valve by a method known as parallel or shunt feeding. This is to prevent loss of inductance and saturation of the core. The anode current is passed through a resistance which is connected between the high tension positive terminal and the anode of the valve. The low-frequency impulses are then applied to the transforiner primary winding by way of a fixed condenser. The response curve of the transformer is affected by the values of the resistance and condenser, and also by the A.C. resistance of the valve used, and the transformer maker's instructions should be followed if maximum results are desired.

The high magnification given by transformer coupling renders unnecessary the use of more than two stages, and low ratio transformers are an advantage both from the standpoint of quality of reproduction and stable operation. See Amplitier.
TRANSMISSION : In Motor Cars. Transmission is the mechanical means by which the power developed by the engine is transmitted to the road wheels.

The usual lay-out of the transmission in a four-wheeled vehicle consists of the clutch, the
gear box, propeller or cardan shaft, and the live or back axle. Two other lay-outs arc clutch and gear hox as a part of the engine unit, and the gear box as a part of the back axle unit. Of the three the second is the most common, and the third is seldom met with. The clutch, of whatever type, forms part of the Hywheel or is directly connected with it. In the three-unit system (independent gear box) the driven member of the clutch is connected by a short shaft to the primary shaft of the gear box. A universal joint is fitted at each end of the clutch shaft so that in the event of chassis distortion unduc strain will not be placed upon the bearings of the gear box and the clutch spigot.

The propeller or cardan shaft, if of the open type, is fitted with a universal joint at each end, one of which is designed for sliding as well as universal movement. This feature is necessary owing to the difference of centres between the axle and the spring anchorage and that of the gear box and the cardan shaft. With the enclosed cardan shaft one universal joint only is provided at the gear-box end, the springs being anchored by shackle plates at both ends. The road wheels of the back axle are driven by either bevel or worm gearing through the medium of the axle shafts and the differential gear.

The clutch and gear box unit construction follows exactly the same lines, except that a clutch shaft fitted with universal joints is dispensed with. A short semi-floating shaft entirely enclosed takes its place, and a longer cardan shaft is necessary, which may be either of the open or the enclosed pattern.

In the third system, gear box and back axle unit construction, the drive is transmitted by a cardan shaft, fitted with universal joints at each end, if of the open type, and onc universal joint at the clutch end if of the enclosed pattern. As a rule the clutch is provided with a short shaft that goes to a bearing at about the position usually occupied by the gear hox. The cardan shaft is universally jointed to the clutch shaft at this point. The object of this is to relieve the clutch mechanism of the lateral strains imposed as well as to reduce the length of the cardan shaft.

Chain transmission is now found only in the motor cycle and the commercial vehicle. For the motor cycle the transinission is either solely by silent roller chain, or by chain from engine to gear box and thence by belt to the back wheel.

To revert to the motor car forms of transmission, there are, of course, other principles that have been tried, such as hydraulic, clectric, and patent devices that give an infinite number of gear reductions, also the friction drive, used on some light cars.

Fluid Flywheel. This is a hydraulic transmission device introduced by the Daimler Co. The mechanism, which replaces the ordinary clutch, consists of two cup-shaped members facing each other-the one, filled with oil, attached to the crankshaft, and the other, enclosed by the driving cup, rotating with the first motion shaft of the gear box. Both cups a re divided off by radial webs into a number of cells, and the adjacent cdges of the two sets of cells (in driving and driven members respectively), are separated by a narrow gap. When the driving cup revolves, the oil receives a circulatory motion and, in passing to the driven member, gives up its energy to the latter, so rotating it. At very slow engine latter, so rotating it. At very slow engine
specds the amount of slip is large, and practi-
cally no drive is transmitted, but as the engine is accelerated the slip quickly diminishes until at normal speeds the loss is only about 2 p.c. Thus the device acts automatically.

Loss of road speed and of general efficiency, of ten attributed to minor engine faults, can frequently be traced to neglect and want of !ubrication throughout the transmission. Sueh parts as the universal joints of the cardan shaft shou!d be frequently looked to, because, apart from rotary movement, they have also to bear a considerable movement that is set up by the varying axle position in relation to the chassis.

It is perhaps seldom realized that when the car is travelling on top gear the clutch shaft and cardan shaft, including all the universal joints, are revolving at engine speed, a fact that easily accounts for the rapid wear that takes place unless proper attention is paid to lubrication.
A worn universal joint should be immediately replaced or rebusled and new pins fitted, otherwise a fracture may easily occur owing to the severe blows imparted by the torque of the engine. With chain or helt drive it is imperative that the sprockets and belt pulleys should be dead in line. All worn parts should be attended to, as it is through neglect of thesc that transmission noise is caused.
With reasonable care and intelligent driving, transmission wear or risk of breakdown should be neg!igib!e in the modern car. The driver, however, of a morlerate powered car who is afraid to use his gear box and forces his engine to labour on hills, or after turning a corner, is placing severc strain upon the transmission system at every point from the clutch to the back ax!c. See Clutch; Differential Gear : Gear; Live Axle: Motor Car : Motor Cycle : I'rope!ler Shaft.
TRANSOM. The prepared piece of wood which divides the upper glazed portion of a window or door frame is usually known as the transom. In casement and French windows, or doors with a glazed opening above, the transom serves also as the door head. In an ordinary window of this type, the transom would be about 6 in. wide and 2 in. thick on the inside, tapering on the top surface to a thickness of $1 \frac{3}{4}$ in. outside the window. This is technica!ly termed weathered, and is designed to throw off the water. A groove is gencrally cut underneath to prevent water running along to the sash, or, to use the technical terms, the underside of the transom is throated.

In many windows, the transom is bevelled off from its highest point. Casement windows or sash windows with a fixed or fan light above are called transom windows. This type of window is often made in mcta!, but the division between the smiall upper portion and the lower portion is still called a transom. See Casement ; French Window, Window.

TRANSPLANTING: Of Plants. Carelessness in transplanting is the cause of many failures in the garden. Plants, whether seedlings or maturc specimens, should be lifted from seed box or open ground with a good ball of soil if possible, but always with their fibrous roots intact. Care of these roots is of paramount importance, for it is their hair-like tendrils that collect the nourishment upon which the health of the plants is entirely dependent.

After plants have bcen lifted they should never be left cxposed to the air, but should

Transplanting. 1. Transplanting streptocarpns : $a$, crocks : $b$, rough ; $c$, peat ; d, fine soil. 2. Lapageria rooted cutting detached from parent, transplanted to pot and plunged in a frame. 3. Transplanted tree carnation layer : a, crocks;

ture between two or more joists or rafters, bridging the space betwcen them with stout timber about 25 per cent thicker and equal in der,th to rafters or joists. These timbers are known as trimmers and should be tusk tenoncd to the others. Intermediate rafters or joists that have to be cut to form the aperture are mortised and tenoned into the trimmers.

In the Floor. Filiets of wood are in the majority of cases fitted around the inner faces of the trap hole with their upper surfaces at such a depth as is necessitated by the thickness of the trap door Notches or openings are cut in the fillets where lec transferred to their new quarters or de- necessary to clear the battens. The upper posited in a shady place. The smaller surface of the floor is cut back so as to reveal kinds should be covered with wet moss and about half the thickness of the joists and this soil, and large specimens such as roses and is then filled in with a mitred framework. fruit-tree enclosed in sacking and drenched with water. They should be replanted at the earliest possible moment, when the sun is down, and watered frequently until they are again established. Syringing during the evening will be of additional benefit, particularly in the case of transplanted evergreens.
TRAP. This word has three main meanings, as far as the household is concerncd. It refers to a piece of mechanism widely employcd for catching obnoxious insects and animals, such as beetles and mice. It means secondly a contrivance used to hinder the passage of foul air from a waste pipe, and finally a small vehicle which is drawn by either a horse or a pony. See Beetle Destruction; Carriage: Dog Cart: Drains; Fly Paper;

The trap door should be very solidly constructed and lit the hole accurately, and when in position should be flush with the normal surface of the floor. It requires to be properly hinged with cellar or trap loor hinges. These comprise three parts; two are fitted to the framework and the trap door, and the third serves as link connecting the other two, there being two hinge points, one near each end of the link. The trimming has to be cut away so that the flap hinge can be sunk into it with its upper surface level with that of the Hoor. Fig 1 illustrates this type of hinge and the mode of recessing the timber for its reception.
When the trap door does not exceed about 21 in. square, ordinary butt hinges may be used. These are fitted vertically into the joint between the trap door and the lloor hoards, as illustrated in Fig. 3. Good stout screws slould be used to secure them, the hinges being of the malleable cast variety, or of some other kind that possesses sufficient strength to stand the strain.
To enable the trap door to be lifted, it is desirable to fit a sinall ring handle, such as that shown in the illustration, and, to prevent the trap door being opened, it is a wise precaution to provide it with a couple of bolts on the underside.
Loft Doors. When fitting a small trap door for access to a loft, or other similar part of a

Mice; Pipe: Rat; Vermin.
TRAP DOOR. The general use of a trap door is to close an aperture through a Hoor, ceiling or roof. It is a horizontal door and usually consists of stout looards jointed together and strength. ened by cross battens. The framework round the trap door must be strong enough to support any load which may be brought upon the floor.

A commonly adopted plan is to make an aper-

Trap Door. Fir. 1. How the flap hinges are fitted. Fig. 2. Making a small trap door of foor board with deal cross pieces. Fig. 3. Simple lifting device consisting of a small ring
building, its width should not be greater than that between two joists, and then it will suffice to fit two cross members betwcen them and secure them with stout spikes driven through the ceiling joists. The trap door can be composed of floor board with cross-pieces of 3 in . by l. in. dea!, screwed to the upper side as in Fig. 2. This rests on fillets in the aperture.

As commonly fitted, the trap door giving access to the space above the ceiling of an upper storey is made of stout matching, and has no hinges. It rests on a lining lixed to the trap aperture and is simply pushed upward into the loft to open the trap.

Roof Doors. Trap doors when fitted into a roof are usually made to lift off bodily, although examples are found in which the hinged flap is used. However it may be arranged the outer surface must be covered with weatherproof material, such as slieet lead or zinc.

A cross sectional view of an external trap door is shown in Fig. 4, the aperture through the roof being framed up with trimmers. The inner faces of the opening are lined with stout timber projecting several inches above the normal roof surface, and covered by a Hashing (q.v.) of lead or other material to ensure a water-tight joint. The trap door

shoult be several juches larger each way than the trimming, and should fit on a lied, or fillet on the under side, to keep it in position. The outer edge of the door is preferably fitted with a small, downward projecting batten of wood and the whole corered with lead. The lead is turned under the outer batten to provide a drip for rain water. Two stout bolts should he located about the middle of the trap. Sec Attic: Cellar: Ladder; Loft.
TRAVELLER'S JOY. This is the popular name of Clematis vitalba (old man's beard), a rampant climbing plant. It hears a profusion of white Howers which are followed by Hufty fruits. This plant is used as a stock on which to graft named, large-flowered varictics of clematis.

TRAVELLING BAG
Several of the receptacles cmploved for luggage are covered by this term, which is applied to suit cases, Gladstone bags and liit hags amongst others.
Bags made of leather should be rubbed over from time to time with neat's foot or harness oil if a polished surface is not requirct, but, as the small leather bag is usually finished with a polished surface, the best treatment is with a good white or brown boot polish. To renovate an old leather bag, the grease and dirt
must be removed with a strong solution of with a soft brush and then polished with a common soda, in the proportion of 2 o7. of soda to a pint of hot water. Apply the soda water with a soft rag when warn, not hot, and if very dirty rub the material with a brush. If the leather is stained, a weak solution of oxalic acid will generally remove the marks, but it should not be applied until the soda solution has been used. The cleaned surface should be washed with lukewarm water and placed in the sun or a warm spot away from the fire to dry.
The leather should now be treated with a wax polish, applied with a solt rag, rubbed in

## Trays: Shapes, Styles and Materials

## Choosing, Decorating and Making for all Household Needs

Several articles in this work describe the materials or processes used in making and dccorating trays, i.e. Inlaying ; Lacquer Work ; Papier Maché; Repousse Work; Tarso. Sec Salver: Shcfficld trays, i.e. Inlaying ; Lacquer Work; Papier Maché ; Repousse Work; Tarso. Sec Salver: Shcfficld
Plate; Silver ; also Ash Tray; Fruit Tray

No housewife need have an ugly tray even in this article. Anykind of coloured embroidery in the kitchen, as the plainest variations in could be substituted for the sill needlework tin, papier mâché, stainless composition and lacquered wood are obtainable in goorl colours at very moderate prices. Oak trays with handles are always useful as waiting trays when laying or clearing the dining-room table.

Vencered and inlaid mahogany trays of Sheraton style should be provided with a glass top to fit inside the border. Such trays when solidly constructed are apt to be rather heavy. If it is desired to use one as a tea tray, it can be laid on the table with the cups, and the teapot, etc., carried in on a lighter tray and placed on it. The same method of service is often resorted to with old Sheffield plate and other metal trays.

A pretty tray with handles suitable for after-dinner coffee service is made of mirror glass framed in polished stecl. This idea can be adapted by the home worker, the tray being made up with a wooden moulding and bottom to fit a picce of mirror glass of desired size. The moulding should be silvered or gilded with metallic paint and handles should be attached as shown in Fig. 4.

Small trays for occasional use are made of papier mâché. These may be bought finished in black with gilt stars, or in sone light colour. A further suitable decoration when something more uncommon is liked is to cut out large roses from a flower scedsman's catalogue, paste and varnish them on to the centre of such a tray, maintaining the Victorian aspect of the papier mûché foundation. Another idea is to embellish the tray with pictorial patchwork. (See page 914.)

There are manv ways of ornamenting trays constructed on the simple methods described
clean cloth. See Luggage; Suit Case; Trunk.
TRAVELLING RUG. A good trave!ling rug is an expensive article when made of thick pure wool. A favourite type has a plaid design with fringed ends. Others are woven in reversible colours. Large numbers of travelling rugs are manufactured for car use in fur fabrics, real furs made up into the standard oblong or square shapes and lined with cloth. leather lined with a woollen check material, and livery cloth, or some waterproof material lined with wool. in this article. Any kind of colourd embroidery under glass in the example illustrated in Fig. 10. A sampler or a group of conventional trces and figures in multi-coloured cross-stitch, a wreath or basket of flowers in tapestry necdlework are a!! effective. A tray cloth in real lace may be mounted on silk to tone with the tea warc. Pen painting and pokerwork, tarso and pencil painting are all art crafts which may be utilized and are quite serviceable when frame and glazed in this manner.

Special decp-sided trays are made for carrying bottles, or decanters with a number of glasses. These trays are provided with movable, raised frames having cut out sections in which the glasses, etc., stand. They are specially useful for carrying drinks into the garden. Other trays are fitted with china or
glass dishes for hors d'oeuvres. Early morning tea trays are often made of stainless composition and surrounded by a wicker-work border. A useful wooden breakfast-in-bed tray is illustrated in Fig. 11. This type of table tray is light to carry and more comfortable to eat from than a tray placed at the side of the bed.

Making Trays. There are several forms of construction suitable for trays. The simplest method perhaps is that in which special metal corners are used in conjunction with a simple moulding having a rounded top edge. Plywood forms the bottom of the tray. Figs. 1 to 4 show progressive stages in making a tray, and are self-explanatory. The moulding, copper corners and suitable copper nails can be had from Messrs. Handicrafts, Ltd., or their agents.

Another simple method of tray construction is to screw mitred lengths of moulding on the top of a wooden base, as in the section at Fig. 5. The base should be of oal-faced plywood a bout $\frac{1}{4} \mathrm{in}$. thick. The use of a rebated moulding is shown in the lower section, the finished tray being seen in Fig. 6. If the decoration is effected with transfers the surface must be thoroughly claned with glass paper and well boiled in with french polish. The position of the transfer decoration can be marked with a chalk line, which should be thin; a length of thread passed over a piece of chalk will provide a suitable line.
The dircctions for laying the transfer should be carefully followed : on no account should the work be hurried, and when in position the wood should be placed on one side to allow the surface of the transfer to harden. A final coat with a transparent polish or varnish should be

Tray. Figs. 1-4. Showing the construction of a tray from the parts supplied by Handiorats, Lta. Fig. 5. Section of a tray corsisting of mouling gerawed. to a base, also a seotion made with cabinet makers' moulding. Fig. 8. Oak framed tray. Fig. 7. Selection of tray mouldings. Fig. 8. Tray handlea Courlesy of Handicrafts, Ltd.
applied, and then the moulding can be placed on the edges, the mitres being carefully planed up on a mitre planing board in order to obtain a clean joint.
The usual handle for this type of tray is seen in the section at Fig. 5. A few other patterns are illustrated in Fig. 8. It is screwed directly to the outside of the moulding, or the plates

Tray. Fig. y. Simple form of decoration with inlaya of different coloured woods
can be let into the wood if desired. It should be sufficient to glue the mitre joints and screw the base to the moulding, but a nail can be driven in at the ends to give further security. A number of tray nouldings are shown in Fig. 7. The uppermost is for screwing direct to the base, the next being a grooved scetion and the third a rebated one. The bottom moulding is for use with metal corners as shown in Figs. 1 to 4.
A varied assortment of mouldings can generally be olitained at the shops which specialize in woodworking materials. As will be gathered from the illustration here given, there are various methods of fitting the base of the tray.
In the tray shown at Fig. 9 the sides should be from $\frac{1}{4}$ in. to $\frac{1}{2}$ in. thick, according to the dimensions of the base, but a tray measuring about 18 in . by 12 in . will not require a greater thickness than $\frac{1}{4} \mathrm{in}$. and a licight of $1 \frac{1}{2} \mathrm{in}$. on the long sides. The ends should be about 3 in . high, shaped to an even curve, and the handle opening cut to about 4 in . long and $1 \frac{1}{4} \mathrm{in}$. lleep. The ncatest method of joining the corners is by the dovetail joint illustrated in the diagram.

Trays. Fig. 10. Pretty atternoon tea-tray made trom a piece of embroidery, backed, framed and glazed. Fig. 11. Hreaklast-in-bed tray of wood, with wicker surround and legs. Fig. 12. Well planned table tray for invalid, with adjustable baize-covered wooden centre and side panniers of wicker for books and work. The tray shown underneath is used in conjunction with the table portion for meals

Fig. 12 bu courtesy of London Association for the Blind

A simple form of inlay decoration is illustrated, consisting of four small squares, each of a different coloured wood, arranged in the form of a square. Thesc may be joined with a length of stringing, but the effect of the corner decoration is quite pleasing. The small squares should be cut from wood planed to $\frac{1}{8}$ in thick and from $\frac{1}{2}$ in. to lin. side, according to the size of the tray. The holes are marked out in pencil and recessed with a sharp chisel, giving the edges a slight undercut so that the inlays will fit tightly in the recess.

Fig. 10 illustrates a tray made up with oak moulding and a woollen botton, over which is placed a piece of embroidery, the latter protected by a shect of glass. In constructing this type of tray the greatest care must be taken to ensure that the glass lies tlat and that the groove or rebate in the mou!ding docs not "bind" the edges at any part.
The honce worker who can manage a little simple basket work may like to construct the useful bed tray slown in Fig. 11. It has a wooden botton, which might be lacquered, or stained and varnished. The table portion should be mads up first, the top fixed, and the basket-work guard then attached to the latter. A devclopment of this iclea is illustrated in Fig. 12, consisting of an invalid's work-table and "breakfast-in-bed" tray. The adjustable sloping work-table is of wood covered in baize. The removable tray shown beneath is used to fetch and carry the meals, and rests on the table, the latter, of course, being adjusted to the horizontal position.
Trays are also used in travelling trunks, drawers, tool chests, etc. In the case of trunks they are usually made with wooden sides to fit inside the trunk and rest on fillets. The bottom is formed with webbing, which is
cooths, which may also be used as table mats, decorated with drawn thread work
stretched from side to side and end to end, and covered with canvas or other material, and in large trays with one or more wooden strips nailed across from side to side to strengthen the bottom.

Trays for drawers and tool chests are made from thin wood resting on fillets which form runners. They can be divided into compartments, and are uscful for storing small articles, or, when used in drawers, to avoid crushing delicate materials. Trays are madc of wire for confectionery and letters and of vulcanite for photographic work.

TRAY CLOTH. Small cloths of washable materials made to fit round, square, oval or oblong trays are provided either as protective mats or to enhance the appearance of a tray. They are also necded when a meal is scrved on a tray. Besides their nominal use they make covers for small dressing-tables and chests, and are often preferred on the afternoon tea-table to a larger cloth, especially when embroidered on linen to match a cosy cover. Scts of tray cloths are also most convenient as place mats for the dinner table.

The housewife can hardly have too many of these charming little cloths, which are so easily marle and laundered at home. They nay be of brightly coloured linen, embroidered and scalloped with white embroidery cotton, of unbleachell linen worked in colours, and with hemstitched edges, of crash with amusing designs in woolwork, or of finest white linen, lace trimmed, or decorated with beautiful Richelieu, Renaissance, or drawn thread work, They may also be inade entirely of tilet, or crochet lace, of oil baize or ralias cloth.

Linen is the most uscful material for tray cloths intended for ordinary household purposes. The set illustrated is nade in coral pink linen with a border design of drawn thread work. Usual sizes, unless made especially to fit a tray, are an oblong measuring 12 in . by 17 in.. or one measuring 15 in . by 20 in . Transfer designs are obtainable in great varicty and to fit different shapes and sizes. Scalloped edges are used for oval and
round tray cloths. See Drawn Thread Work Embroidery; Heınstitch; Pattern Printing; Raflia Work; Scalloping.

TREACLE. The uncrystallized syrup that drains from raw sugar in the process of refining, and is known as treacle, contains a large proportion of saccharine principle, and is valuable as an article of houseliold diet. I is cheaper than sugar for many purposes.

The uses of this syrup in cookery are manifold. It is used in making all linds of ginger cakes, gingerbread, and brandy snaps. It is often adcled to the pickle employed for curing hams and spiced becf. The finer variety of syrup known as golden syrup is usually employed for making roly-poly puddings or treacle tarts, but the pure brown treacle will be found superior to a highly refined syrup for most puddings or for calies. The very darkest form of syrup, called black treacle, is not suitable for table use.

Treacle Fruit Cake. Gollen syrup or treacle is used to mix this fruit calic, which is made according to the following directions:

Treacle Fruit Cake. A wholesome caise for nursery tea
Wash 6 oz. each currants and sultanas, wipe them in a clean cloth, and put them aside to dry. In the meantime, sieve together 1 lb . flour and $\frac{1}{4}$ fiat teaspoonful carbonate of soda; rub in $\frac{1}{2} \mathrm{lb}$. margarine until the mixture resembles fine breadcrumbs.

Add the fruit, previously stalked, and 2 oz . candied pecl cut into small picces, mixing all these ingrerlients well. Break 2 eggs into a small basin, whisk them well; then add $\ddagger \mathrm{lb}$. syrup or treacle, and continue whisking. Dissolve $\frac{1}{1} \mathrm{lb}$. sugar in 1 gill milk, add these to the eggs, and when they are thoroughly mixed pour them into the dry ingredients and beat the mixture for a few minutes before turning into a large, round cake-tin previously greased and lined with greased paper.

Bake the cake in a moderately hot oven for about 2 hours, lessening the heat after the first 20 min . If it becomes brown on top before it is thoroughly cooked, cover it with a picce of paper. When ready, lift it out of the oven on to a calip-sieve and leave it to cool.

Treacle Pudding. Mix together 6 oz . flour, a little more than 2 oz. finely chopped suet, 3 teaspoonful ground ginger, a pinch of salt, and 1 saltspoonful bicarhonate of soda. Then add an $\mathrm{cgg}, \mathrm{l} \frac{1}{2} \mathrm{oz}$. treacle, and enough milk to mix the whole to a soft consistency. Turn it into a greased basin, cover it with a piece of greased paper, and steam it for about 2 hours. Scrve it with heated golden syrul or golden sauce (q.v.).

Anotlier variety of treacle pudding is made by sifting $\frac{1}{\frac{1}{2}} \mathrm{lh}$. flour with $\frac{1}{4}$ teaspoonful salt into a basin, adding $\frac{1}{2} \mathrm{lb}$. finely chopped suet, $\frac{1}{2} \mathrm{lb}$. raisins stoned and cut small, or $\frac{1}{4} \mathrm{~h}$. raisins and an equal amount of cleaned and picked currants. Stir together 3 tablespoonfuls treacle with $\frac{1}{2}$ pint cold water, and with this mix the dry ingredients in the basin to a dough. Grease a pudding basin, turn the mixture into it, cover with a cloth, and boil for 4 hours. Serve with sweet or golden sauce.

## Treacle Tart, a cheap and attractive sweet

For Palmeston pudding, another form of treacle pudding, equal quantities of breadcrumbs, suet, and treacle are reguired. The pudding is boiled in a greased loasin covered closely with a cloth for about 3 hours.

Treacle Roly Poly. This is made in the same way as jam roly poly (q.v.), and $\frac{3}{4} \mathrm{lb}$. treacle or golden syrup is required. This should be niixed with 3 oz. lreaderumbs and $1 \frac{1}{2}$ teaspoonfuls lemon juice, being first warmed in a pan if the weather is cold. Golden sauce should be served with it scparately.

Treacle Tart. Some short crust pastry, $\ddagger \mathrm{lb}$. golden syrup or treacle, 2 tablespoonfuls line breaderumbs, and $\frac{1}{4}$ teaspoonful ground ginger are necded to malie a treacle tart. Roll out the pastry to a round about $\frac{1}{4} \mathrm{in}$. in thickness, use some of it to line a round greased tart-tin, and decorate the edges with a fork. Mix the breadcrumbs with the ground ginger, add to these the treacle, previously warnied, and pour the whole into the lined tin.
Roll out the remainder of the pastry, cut it into strips about $\frac{1}{4} \mathrm{in}$. wide, twist each of these two or three times, and then lay them across the tart so that they form a trellis-like pattern, as shown. Bake the tart in a hot oven for 20 min ., and then turn it out of the tin. It may be served hot or cold. See Golden ludding; Pastry; Suet Crust; Toffee.
TREADLE. Used in foot-driven sewing machines, fretsaws, lathes. and other small machines, for propelling a $\| y$-wheel, the treadle or foot-motor is a hinged plate fixed to a base or to the framework of the machine and attached to the fly-wheel by a connecting-rod known as a pitman.

The treadle is balanced on a spindle to give an up-and-down movement to the pitman, and is variously shaped from a single foot rest of the portable treadle here illustrated, the double foot rest fitted to some makes of sewing machine, to the heary bars, and pierced iron plate of the lathe. The portable treadle driving wheel is useful in the amateur's workshop for driving a polishing head, a small circular saw or drilling machine, but it must be securely screwed or bolted on the fioor.

Inconvenience is often callsed when using a treadle by the fly wheel stopping

Treadle. Portable treadle with a single foot rest Courlesu of R. Melluish, Lld.
at dead centre. It is not experienced to any cxtent with a light machine but generally with a lathe fitted with a heavy fly-whecl. The best method of overcoming the dead centre on the crank and so bringing the treadle into the correct position for starting when the inachine is at rest is to clamp a weight on the fly-wheel so that when the machine is at a standstill, the treadle $u p$, and the crank just over the top centre, the weight is at the bottom of the whicel. A sharp downward push on the treadle will send the crank over the bottom centre, and the impetus given will carry the wheel round. See Fretwork: Lathe: Sewing Machine.

TREE: For the Garden. Trees should never be planted close to a housc. Not only when fu!ly grown do they hinder the free

Tree Carnation. Blooms of the variety Einchantress, a beautiful greenhouse carnation. See below
passage of light and air, as well as inducing dampness, but their presence is a menace to the structure of the building itself.

As a ru!c, the roots of a tree spread just as far underground as the radius of the branches ahove. In the course of time, therefore, this spread of roots is quite likely to underminc the foundation of a house, and to render it unsafe. Oaks and yews are the least desirable trees to have near houses.
Some of the most attractive trees for planting in the garden are various Conifers; for example, cypress, deodar cedar, spruce and silver fir: hawthorn, laburnum, catalpa or Indian bean tree, bronze-leaved plum (Prunus Pissardi), ornamental crab (Pyrus foribunda and others), ornamental cherry, scarlet oak (quercus coccinca), variegated maple (acer negundo variegatum), and green and variegated hollies. See Apple; Fruit; Grafting; Hazel ; Laurel; Rose ; Syeamore, etc.
TREE CARNATION. This name was used to distinguish the original type of winter and spring-flowering carnations grown under glass, a type which has bcen to some extent superseded by the perpetual-flowering carnations. They need a minimum temperature of about 50 degrees, and are propagated by cuttings inserted in sand beneath a propagating case in the greenhouse. A few of the finest varieties are Spectruin, red; Laddie, salmon; White Pearl, white; Topsy, crimson; and Enchantress, light pink. See Carnation.

TREE LUPIN. This vigorous hardy shrub Fig. 2. There is another form taken from the grows quickly and soon forms a large spreading bush 4 ft . or more high. It needs plenty of room and is scarcely to be recommended for

small gardens. The Howers of the typical kind (Lupins arboreus) are pale yellow and fragrant: they are produced very frecly in May and June. Somerset is an improved yellow variety. The variety Snow Queen has white Howers. Thesa plants thrive best in well-drained soil and dislike being disturbed; they are easily propagated by seels sown out of doors in spring. Straggling shoots should be cut back in March.

TREE OF HEAVEN. This is the popular name of a hardy leaf-losing Chinese trec (Ailanthus glandulosa) which will reach n height of 50 ft . or more. It is valued for its long pinnate leaves and red fruita in autumn. This tree, when young, is often hard pruned each spring and restricted to one now stem. for under this treatment the leaves arc exceptionally fine, though its height docs not then exceed 5 ft . It does well in town gardens and flourishes in ordinary soil. Propagation is by suckers in spring, by lagering in summer or by sowing seeds.

TREE PEONY. This shrub (Paeonia moutan) bears immense double or single Howers in spring. It is scarcely suitable for general planting, for it starts into growth carly and the young shoots are liable to be damaged by late frost. It needs lonmy soil and a position in which the morning sun will not reach it. It is a Japnnese shrub and the numerous varieties have chiefly Japlancse names. Paeonia lutea is a handsome tree
 peony from China and bybrids have been raised between this and the common trec peony.
TREFOIL .
The trefoil, which is a favourite form of Gothic ornament, as employed in architecture, is an ornamental foliage of threc divisions that is based, like the quatrefoil, on a geometrical construction. The simplest form of it is shown geometrically in Fig. 1 and a pointed form often scen in stonework in

Fig. 2. There is another form taken from the clover leaf in Gothic carving. It may be used with good effect in relief carving and is one of the most suitable motifs for the amateur woodcarver. See Quatrefoil.

As an ornamental support for flowering plants trellis work is much alin to lattice and rustic work, although the latter term is generally applied to the construction of articles of rough, natural material.

As a rule trellis work is carried out with relatively thin prepared timber, in which sawn plastercr's laths play an important part, hut the term is often a pplied to work carried out with wood in its natural state. The work consists cssentially of interlacing, cither at right angles or diagonally, thin strips of wood, which are fixed to some form of support or

Trellis. Figs. 1 and 2. Two methods of Gxing the laths: in one they cross at ripht angles, in the other diagonally
rough grounds. In sone cases the strips are not actually interlaced, but are placed so that they cross over one another either at right angles or diagonally, and the appearance of interlacing is obtained.
A general idea of the method of lixing the laths is given in Figs. 1 and 2, where they cross at right angles and diagonally. The joint where they cross is completed by driving a small nail through it and clenching it. The ends should be fixed to somas supporting frameworl. The common expanding diagonal trellis can be obtained so cheaply that it is only when some more robust and permanent form is desired that the worker will be called upon to make up this type.
lig. 3 shows trellis work in prepared timber, which is very suitable when its purpose is to act as a screen rather than purely as a support for plants. The framework has grooves worked on the inner edges in which the trellis is fitted. The latter is carried down to just below half the total height, and the lower portion is filled in with match boarding. The framework, which is made from specially prepared timber, is joined together ly stub tenons cut in length to just the depth of the grooves, the joint being strengthened with nails.

The length and height of the whole should be first decided upon, and a decision made as to the number of intermediate uprights that will be required. The various lengths are then cut off, always allowing for the tenons. The !atter are marked out, using a square to get them true. and sawn with a tenon saw. The thickness of the tenons may be obtained from the grooves into which they fit. and it is advisable to cut them rather full so that a tight

TREILLAGE. Literally this is another name for trellis but it is applied specia!ly to a frame of stout wooden uprights crossed with squared laths of ligbter substance and adapted for the support and training of fruit trees.

## Trellis and Trellis Work

## Structures for Screening and Beautitying the Garden

A number of articles in our Encyclopedia have reference to one or other of the uses of this form of woodwork. for instance Arch; Fence; Garden; Pergola; Porcl1; Roof Garden; Rose Garden. Sce also Rustic Work; Summer House
joint is obtained, affording the necessary strength and rigidity. The top rail, which is bevelled on hoth edges, runs through the whole length, as in Fig 3, the micldle or intermediate uprights being jointed into it as in Fig 4, and the end uprights as in Fig 5 . It should be noted that the end uprights are grooved on one edge only. Fig. 6 shows the details of the jointing of the centre rails, which are niso bevelled on both edges, and are further rebated on one of the lower edges to take the matchboarding. The lower rail is also rebated on the upper edge as in Fig. 7. and is jointed to the end upright as there shoan : the intermediate uprights are tenoned into it, mortises being cut for this purpose. These latter should he carefully measured off and miarked out in accordance with the length of the centre rails so that the uprights are perfectly vertical when they are fitted in position
The trellis work may be composed of plas. terer's laths, or a quantity of narrow, thin stuff may be obtained for the purpose Whichever is used, it should be obtained in conjunction with the timber for the framework, since the trellis fite into the gronves in the framework The width of the grooves equals double the thickness of the laths, since one series of the latter is placed llat on the other. It is not always necessary to nail every joint where the !aths cross, especially where a very close mesh is required, each alternate joint being usually sufficient. The matchboarding is secured after the main framework has been erected by nailing. After the whole is in position, it may be coated over with one of the various preservative stains.

An onk trellis is shown in Fig. 8, suitable for erection at a boundary or in place of a solid wall. It is supported at intermediate

Trellis. Fig. 3. Type of trellis work composed of prepared timber which will be found exceedingly lettering refers to details of providing a screen. The
disiances by brick pillars. The horizontal positions of the supporting posts. The next into the ground. After the posts have been members are alternately placed on the outer stage is to prepare the posts to the requisitc erected in position and well rammed and conand inner sides of the uprights, and the height. this depending upon the nature of the solidated, the positions of the horizonta! lower rail is supported by short uprights surround and the plants to be trained thereon. members are decided upon. and these are built into the top of the brickwork The If such plants as rambler roses are to be placed in position and naile. 1 to the posts. The whole is toned down to a dark colour, and when covered with climbing plants forms a very effective screen.

The trellis in Fig 9 is erected against the sides of a house. for the purposes of training creepers. It is built up in set designs with a border and is sccured to a gromidwork of hattens applied to the walls. The porch on the right is of prepared timber, mortised together, rooled in at the top with timber and covered with one of the patent rooting materials. A fairly heavy moulding is mitred round at the fopl, the tre!lis built up in sections and afterwards secured to the who!e. When deciding upon trellis to be made up in sections and applied to a wall, careful measurements should he made for the position of windors, doors, drain pipes and the like, and allowance mado for them : also for the rough grounds to which they are to be fixed, since this materially enlarges the length required for the trellis. A method of fixing the grounds is shown in Fig. 10, which illustrates the use of a spacing gauge.

Rustic Trellis. The trellis made of laths has many applications as a screen, but natural appearance given by rustic construction is very pleasing. and a vustic trellis is often more in harmony with the garden and its surroundings. A completed trellis is shown in lig. 11, stages in its construction being illustrated in Figs. 12 and 13.

Having obtained suitable and sufficient material, the first step is to mark out the position in which it is required to place the screen. This can be done in the ordinary way with a line and a few pegs, marking out the
 horizontal members should be less in diameter than the posts, and of such length that the joint made between any two comes at one or other of the upright posts. If the poles are ot any considerable thickness, the ends can be trimmed off flat and nails driven through both
 into the posts.
Having fixed these pieces, which in the example illustrated
trained over the screen, the posts may be are located one along the top of the posts anything up to 8 ft . or 9 ft . in height, and the and the other about 3 ft . above the ground, screen illustrated has been constructed on the principal cross pieces are placed in this assumption It is a good plan to treat the position and fixed to the posts or horizontal boltom of the posts with either tar or creosote members with stout wire nails. This The posts should be sunk from 18 in . to 2 ft . operation is illustrated in Fig. 12 These

Trellis. Fig. 8. Type of rectangular trellis carried out in oak. Fig. 9. Example of trellis work applied to the walls of a house, the porch being designed in.the same medium to harmonize. Fiz. 10. Use of spacing gauge, fixing the horizontal strip to vertical. Fig. 11. An example of a completed rustic trellis forming an excellent support ior rambler roses, etc. Fig. 12. Fixing principal diagonal members. Fig. 13. Fixing lighter diagonals into trellis screen
cross pieces may either be fixed in their natura round shape or flat tened on one side

The spaces bet ween the main cross members are filled in with lighter material in much the same way lixing these in an X fashion and, if possible. interlacing them one over the other until the required degree of closeness is obtained ( Fig 13)

TRELLIS: In Needlework. This filling stitch is used to cover large spaces in embroidery on linen and is worked on counted threads of the fabric It consists of horizontal and per pendicular lines o! working threads held down by a cross stitch where the lines meet. In some designs a small running stitch crosses the junction of the lines. Two other filling stitches with epaced working threads set diagonally are illustrated in page 684, Figs. 4, 5,

The threads of the ground material should be counted both ways, so that they are set evenly apart. If the small stitches which form the tirst half of the crosses are worked in one direction in one long row, and in the reverse direction on the return journey, all the crosses will be worked in the same way and give a more even effect.
The illustration shows the needle in the correct position, working downward and form ing the cross stitch at the junction of two lines See Cross Stitch; Embroidery : Laid Work

TRENCHING. This is the best method of cultivating garden ground; it ensures the finest possible Howers and vegetables. Those who grow for exhibition trench the ground three spits (about 30 inches) deep ; for orllinary purposes it is suflicient to trench two spits (about $20 \mathrm{in}$. .) deep. If the land has been in cultivation for some years the upper soil may be brought to the surface and the surface soil buried. When trenching new ground, however, the layers of soil must be kept in the same respective positions.
When tronching cultivated land the first thing to do is to dig out the soil two spits deep and 2 It. wide; the excavated soil is placed near the other end of the plot. The bottom of the hole is forked over and leafy garden rubbish is mixed in. The next top layer of soil is transferred to the first trench and the next second layer on top of that. Thus the first trench is filled and the second is emptied. Eiach trench is dealt with in the same way. the last trench being tilled with the soil first talien out.
In trenching new land the turf should be stripped off and stacked for a year. The first trench is dug two spits deep and 2 ft .
wide and the top layer of soil is also taken off the next strip, hoth lots being placed at the other end of the plot. The second layer of soil from the second strip of ground is put in the first trench and the top soil from the third strip of ground is placed on top of it

Trellis in needlework. Method of making this stitch, useful for Method of making th
overing large spaces

Thus the lirst trench is filled and the layers of soil remain in the same respective positions. Farmyard manure or hop manure should be mixed with the second layer of soil when trenching hoth new and old land. When trelsching is finished new land must be limed, using one bushel to three rods. The lime should be turned in with the garden fork. The best time for trenching is in autumn and winter. See Celery : Digging ; Spade.
TRESPASS. There are threc kinds of trespass in law, namely, trespass to land, to goods, and to the person. The last of these is more usually called assault. Trespass to goods consists of any actual taking of or a direct and immediate injury to a nother's goods or chattels. For instance, it is equally trespass if A rides away with B's horse or hits the animal and causes it to run away. If A throws a stone and hits B's head it is trespass.

Remedies for Trespass. The remely for trespass to goods is by an action for damages. The damages recoverable are, where the goods are taken away altogether, the value of the goods; and where they are merely injured, then the amount of the damage done to them. An action for trespass to goods will not lie unless the plaintiff had the goods in his possession at the time of the trespass.

It is, however trespass to land that is usually spoken of as trespass. This is committed where anybody, whether wilfully or otherwise, goes upon the land of another without his permission. The word land includes houses and other buildings. This offence, like trespass to goods, is an interference with possession rather than with owner ship, so that the tenant of a house o land can bring the action.
The remedy is an action for damages, and these damages
are by no means limited to the actual peeuniary loss sustained by the occupier of the land or house. Thus, very heavy damages have been awarded against a trespasser who walled into another man's ground and paraded up and down in front of his windows, into which he stared in an olfensive manner. In the same way, when a monev lender has seized furniture under a bill of sale, and has wrongfully kept a bailiff in possession for several days, he has been made to pay very heavy damages, and this although the bill of sale was only void on a technicality

Besides actions at law, the householder or landowner has the right to protect himself against a trespasser by turning him out, proviled that he only uses as much force as is necessary, and no inore. He sloould lirst be requested quite civilly to go out.

Trespass is not generally a crime, in spite of the common notice that "trespassers will be prosecuted." It is, however, an ollence to trespass on to land belonging to a railway company or on to any land if damage is thone to the land, or in pursuit of game. It is also an offence to drive a motor vehicle on to private land or on to a common.

Trespass by Animals. The owner of tame animals is liable to an action of trespass if he allows them to escape on to the land of his neighbour, unless the neighbour was under some duty to maintain a fence and failed to do so, whereby the eattle, etc., were able to strixy upon his land. This does not apply to logs or eats. If cattle are being driven along the highway, their owner is not liable for any damage they may clo or for trespass at all if, without any negligence on his part, they stray upon unfenced land

Anyone who takes upon his own land some thing which is liable to cause injury if it escapes, must pay damages if the dangerous thing does escape and goes upon the land of a neighbour, and this whether there was negligence or not. The best-known case was where the defendant constructed a reservoir upon his land and it cracked and the water cscaped and flooded the workings of an adjoin ing mine. The owner of the reservoir was held liable, although it was no fault of his that the reservoir gave way. A trespasser must take the land as he finds it and will have no remedy if he injures himself by falling into a pit or quarry

Man Traps, etc. Even a trespasser is entitled to be protected against man traps, spring guns, or other engines calculated to do bodily harm or to destroy life. Anybody who sets such a device on his laid with intent that it shall destroy or inHict bodily harin upon a person coming in contact with it, is guilty of a criminal olfence, and is liable to penal servitude for not less than three or more than five years, or imprisonment for not more than two ycars with or without hard labour It is equally an ollence to leave such an engine in position if it has been set by a previous occupier.

The houschokler is, however, entitled to protect his dwelling house by setting a man trap, spring gun, or other engine between sunset and sunrise. Nor is there any law to prevent him setting traps for vermin, and a trespasser who walks into a rat traj has no remedy if he is hurt
TRESTLE. In building operations and redecorating, the trestles mostly used take the form of a self-supporting pair of steps. They arc most usually employed in pairs, placed at a convenient distance apart, generally from 6 to 8 ft . span. Scaffold planks or other strong boards are rested upon the treads of the trestles to form a platform.

A strong trestle of a nother type which is useful for such purposes as the support of a wash tub is illustrated in the following page

Trestle. Esample of a strong trestle suitable for domestic use

It is substontially built from stont timbers, the top about 9 in. wide and $2 \frac{1}{2} \mathrm{in}$. thick; the legs about 4 in . wide and 2 in. thick; the cross pieces 3 in . wide nnd 2 in . thick; the whole being securely halved and screwed together. It will be noted that the logs splay in two different directions, spreading out wards like the letter $A$. When viewed from the side and from the front they incline outward from the top part, this being done to give greater stability: A pair of light hinged tiestles is used to support a table such as that deseribed in the suceceding article. See Scallolding; Steps.

TRESTLE TABLE. There are many uses in the ordinary home for a table supported on a pair of trestles such as that illustrated in Fig. 1. It may aerve for the support of a table tennis table, and may also be used as an emergeney talile at Christmas or other times. To the amateur constructor it affords a temporary support for work, and when papering a room it is most uscful as a pasting board.
A complete set of the compononts required for the trestles is illustrated in Fig. -2, which also gives the leading dimensions. The legs are of deal or other tough wood measuring 2 in. wide and 1 in. thick. The crosshars are of similar material, but those on the top should be 2 in . deep and $1 \frac{1}{2}$ in. thick. The crossbars can be dowelled and serewed to the legs, which are glued and serewed into notebes or housings cut in the top bar.

When the timber has been prepared to the correct length and size, planing it up on all four sides, the positions for the crossbars at the lower part of the log are marked out. It will be noticed that the logs of the trestles are splayed in order to aflord stability. In addition, considerable care must lic taken so as inget the notches in the
lop picces cut at the proper angle, and the ends of the crossbars also must meet the legs at a similar angle.

One of the side pieces and a crossbar are grasped in the vice in the manner illustrated in Fig. 3, at the proper angle, and both of them arc drilled through with a brace and bit as shown. A dowel pin is driven temporarily through this hole and a second drilled about 1 in . from it. All the dowel joints are prepared in the same way and are assembled hy inserting the dowels into the side pieces, placing the crossbar against them, and after coating the joint faces with hot glue they may be cramped up until set

The top pieces are prepared and notehes cut in them, so that the legs can be fitted. The legs should lit very closely against the shoulders of the slot in the top bar, to add to the stilfness and general stability of the structure. When fitted, they should be glued and screwed in place. After the glue has set hard, any overhanging or projecting portions should be planed off.

The final operation is to hinge together the two members of each trestle with stout butt hinges. This is best accomplished by placing the two top edges together, laying the hinges llat on the upper surface with half on cach crossbar. Holes are then drilled and the screws driven home. Two serews should be placed in each hinge as a start and one of the
kgs lifted up, as shown in Fig. 4, to sec that it folles back properly. Any necessary corrections in the alinement of the hinges should be made, and the remainder of the screws then drivell home.

The table top is constructed from a few lengths of tongued and grooved floor board, the outer edges planed up smooth, and the cuds and the centre strengthened by cross battens of wood about 1 in . thick and 3 in . or 4 iin. broad. To prevent the legs of the trestles from opening too far, a stout cord is threaded through holes drilled through the centre of each of the lower crossbars and prevented from pulling out by tying a knot in each end of the cord. The length of both the cords should be equal, to ensure the heights of the two trestles being uniform. See Folding Table; Table.

TRICHOMANES. This is the name of a group of beautiful filmy ferns which are grown in glass cases in a shady greenhouse in an exceptionally inoist at mosphere. They should be set in well-drained pots or earthenware pans, in a compost of sandy peat with pieces of sandstone intermixed. Propagation is by spores, at any time during the year, or by division of the roots in early spring. On no account should be plants be syringed.

TRICHOPILIA. The small evergreen orchicl called Trichopilia flourishes in the

intermediate house. It has flowers of various colours, some of which are slightly fragrant. They grow best in pots or baskets hung from the roof of the grcenhousc, in a mixture of peat, sphagnum moss, and charcoal. The necessary average temperature is $50^{\circ}$, rising to $60^{\circ}$ during the summer months or growing period. Trichopilia is propagated by division of the preudo-bulbs in early spring, when the plants should be repotted. See Orchid.

TRICYCLE. For the use of children tricycles are made in considerable numbers as well as for adults of both sexes who are unable to adapt themselves to the bicycle. The modern type of light tricycle is as easy to propel as a bicycle. A diflerential axle allows the rear wheels to turn independently at different specds when going round a bend. The frame is made generally in two sizes, 22 in. and 24 in ., and the wheels are usually 26 in . The same methods of cleaning and ailjustment used for the bicycle also apply in the case of tricycles. Sce Bicycle: Tire.

TRIFLE. A sweet with a basis of spongecake, trille can be made from a variety of added ingredients and is usually named according to the predominant Havour Whipped cream, almonds and other nuts, angelica, crystallized flowers, and glacé fruits are all used in the decoration of triffes.

A good plain trifle can be made by splitting six small sponge cakes, spreading the cut sides with jam, and arranging the lower halves in a glass dish with the cut sides uppermost Boil up $\frac{1}{2}$ pint milk, soak the cakes in the dish with some of it, put on the top halves, and then pour on the rematinder of the milk Prepare some custard with 1 pint milk, 1 tablespoonful custard powder, and 1 oz . castor sugar, flavour it with a icw drops of vanilla and let it cool. Then pour it over the cakes, set the whole aside until it is colcl. and decorate it with glacé cherries.

Another varicty of trifle is made either from a Siwiss roll or two jan sandwich cakes. Cut the calic into blocks each about $\frac{1}{2}$ in thick, heap these on a glass dish, and pour over them I pint custard, basting them until they are well soaked. Whisk $\frac{1}{2}$ pint cream until it thickens, stir into it the stiffly whipped whites of 2 eggs , and add sugar and vanilla llavouring.

Heap the mixture all over the soaked cake, lecorate the top with a few ratalias, and blanched and shredded almonds. If liked, the quantity of cream may be lessened and the cake may be soaked with fruit syrup flavoured with ratafia before the custard is poured over. See Banana Trife; Fruit Trifte ; Ratafia.

TRILLIUM. This is the botanical name of the wood lily or trinity Hower, a charming hardy plant for the rock garden; it bears large, three-petalled Howers in spring. The roots should be planted in autumn in slight shade in soil with which peat and leaf-mould have heen mixed. The common wood lily is Trillium grandillorum, 12 in., with beautiful white Howers: sessile, 9 in., has reddish blooms, and those of nivale, 10 in ., are white.

Trillium. Curious three-petalled flowers of the wood lily (Trillium nivale), a low-growing plant for the rock garden

TRIMMER : For Cutting. Various kinds of trimmer are made for cutting paper, prints, card, and wood. A useful tool of this litud for photographic prints is made with a curved linite blade attached to the side of a llat base, but as the edge of the blade requires frequent sharpening it is generally more convenient to usc a detached linife.

TRINKET. The word trinket is used to describe a small ornament usually of slight value, as for example the cheaper kinds of

Trifle. Plain variety of this party sweet
brooches, bangles, fancy pins, and necklaces A sniall box suited for holding such articles and to stand on the dressing table is known as a trinket box, but for these there is no conventional pattern. See Enamelling.
TRIPE: How to Cook. Tripe is the inner lining of the stomach of the ox or cow As a food it is tender and easily digested. There are various kinds, named according to the part of the stomach from which they are taken. Honcycomb, blanket, and booli tripe are perhaps the best known.

As sold in the shops, tripe is usually partially cooked, but if totally unprepared it needs careful cleaning in three or four dilferent waters and should be left to soak in clean, slightly salted water for two or three hours It needs long preliminary boiling. As many as 16 hours may be required before the tripe is tender. After cleaning, it should le covered with cold water, brought to the boil. then strained, and more cold water added. This process should be repeated until the tripe has lost its unpleasant smell. It should then be covered again with cold water and cooked until tender. For prepared tripe the process is simpler. The cold water needs to bestrained off only once, and two or three hours' slow cooking is usually sulficient The tripe may then be prepared.

Tripe and Onions. The most popular method of cooking tripe is to stew it with mills and onions. 'To do this, boil $: 2 \mathrm{lb}$. tripe for two or threc hours, adding. after about one hour's cooking, three or four pecled and quartered Spanish onions. When this preliminary cooking is over, cut the tripe into pieces of a convenient size and chop the onions. Melt 2 oz . butter in a sauccpan, thicken it with 2 tablespoonfuls llour, and when the two are smoothly mixed strain in 2 large breakfastcupfuls of the stock in which the tripe was cooked. Stir the sauce until it boils, add 1 breakfastcupful

milk, scasoning to taste, and the pieces of tripe and onions, and cook all slowly for about 20 min . Serve the whole on a liot dish.
Casserole of Tripe. Tripe can also be cooked in a casserole. Slice six onions and fry them brown in lutter or dripping. Then, having cit the prepared tripe into pieces, put it into the casserole. where the onions have been placed, and add to it 1 pint white wine, one or two carrots cut into small pieces, a tealspoonful cach chutney and salt, a few peppercorns, and a bunch of herbs. Shut down the lid very tightly and, if necessar!, elose the edges with a thin strip of dough so that no steam can escape from the interior. It should then be cooked in in gentle oven for four or five hours. If made the day before, it can be reheated, the fat being first of all skimmed from the surface. It can be served in the casserole, the herls having been first removed.

Curried Tripe. To serve tripe as a curry cut $1 \frac{1}{2}$ Ib. prepared tripe into small pieces. Melt $1 \frac{1}{3}$ oz. butter in a pan, cook 5 tablespoonfuls minced onion in it, and when it is lightly browned add $\frac{3}{4}$ tablespoonful cury powder and the sance quantity of flour. Fry all these ingreclients well lefore pouring in :3 gills white stock and half that quantity of milli. Stir the whole well until it boils, and then add seasoning to taste. Add the tripe to the sauce and cook it slowly until it is heated through l'reshly boiled rice should be served with this dish, either as a garnishing horder or handed separateiy. See Casserole; Curry

TRIPOD: For the Camera. 'The amateur photographer who attempts anything but snapshots is immediately faced with the question of the kind of tripod to use. There are imumerable varieties on the market, few of which, however, fulfil a! the reguirements of the ideal ripod.

Such a ripod should be of very light weight and fold up compactly : it should cxtend to $4 \frac{1}{2}$ to 5 ft ., and when extended should be rigid and able to support without vibration the

Tripod. Fig. 1. Aluminium tripod witu automatic closing action. Fig. 2. Folding tripod made from sections of brass tubing. Fig. 3.
Courles! of Westminster Plioho. Exc
weight of a grood-class $\frac{1}{4}$-plate cancra, using metal slices and glass plates. The old fashioncd folding wooden tripod on which $\frac{1}{2}$-plate and larger fiedd cameras were supported met none of these requirements except that of rigidity.

The most successful of modern tripods aie those made in metal, brass, or almminium, generally in tubular, telescopic form. A very good example is made in triangular aluminium Tulics (Fig. 1). It is extremely light, rigid when open, while its automatic closing action overcomes the tediousness of closing section

bysector which was experiencert with earlier forms of aluminium tripods. The photograph shows one leg

> Tripod. Figs. 4 and 5. Metal tripod which folds up to form a walking stick. Fig. 6 . Ingeniously designed tripod in larchwood, which folds compactly together and forms a walking stick. Fig. 7 . Small scale view of the walking stick tripod extended for use Figs. 4 and 5. Courtesu of Westminster Photographic Exchange, Ltd. Fias. 6 and 7. Courlesy of A Adams i Sons, Ltd. of the tripod
closed up, the right leg with each of the a level. The little and nearly uselcss viewfinder 5 sections pulled out a little, while on the centre is largely responsible for this fault, and the leg is shown the small press button, pressure effect is that 90 per cent of the photographs upon which releases the catch and allows all taken have the view point of a being with cyes the sections to be thrust home in one in his stomach instead of in his head. If the movement. This tripod extends to the useful tripod itself has not sufficient extension, it height of 5 ft . when open.
The tripod-using photographer, whether amateur or professional, requires that the burden of photographic apparatus he is to carry about shall be made as convenient is possible. Accordingly, various forms of tripod close into walking sticks and other easily portable forms. An extremely compact form is the Zciss-Ikon (Fig. 2), which has a Hat metal plate for the head, on which the camera is very firmly based. It only measures 12 in. when closed, and its sections of brass tubing open to nearly 5 ft . Being made of brass, it is somewhat heavy to carry.
A still more compact camcra stand is the Ensign Featherweight llat tripod (Fig. 3), which, measuring only 11 in . when closed in its case, extends to 42 in. It provides a folding flat head giving rigid support; its weight is 17 oz .

Ingenious varietics of tripods which fold up into the form of a walking atick are shown in Fige. 4-7, closed and open. That shown in Fige. 4 and 5 is of metal, the handle and ferrule screwing off top and bottom. The three legs then separate and the extensions are pulled out, as in Fig. 5. The walking stick tripod illustrated in Figs. 6 and 7 is a handsome specimen maile in hardwood.

For small hand cameras a device such as the Kodak Optipod or Kodapod illustrated in page 939 , make good substitutes for a tripod when fixed to a fence,

T'ripod. Fig. 8. Ball-sau-socset head to be screwed on top of tripod
should either be mounted on a raised object or an extension rod added to the top.

A useful accessory is the ball-and-socket head, such as that shown in Fig. 8, which can be screwed on to the top of any tripod. This enables all levelling to be done after the tripod is set up. With the ordinary tripod the camera has to be levelled by moving first one leg and then another, and on rough or slippery ground this is apt to the an extremely tedious business. With the ball-and-socket head the tripod can lo set up in any position, and the camera is quickly and simply levelled and pointed in the right direction by releasing the screw on the side of the socket, tightening it up again when the correct position is found. Moreover by means of the slot scen in the side of the socket the camera can be turned completely over on its side. so that photographs can be taken in either horizontal or vertical position without the necessity of unscrewing the camera from the tripod head.

When using a tripod indoors on linolcum wood, or stonc floors, it will be found that the metal pointed feet have a lendency to slip. This is simply overcome by using a piece of string with four loops tied in it, one at each end and the other two at $\frac{1}{3}$ of the distance from each end. In use the two end loops are slipped over the foot of one of the tripod legs and the other loops ovor the other two legs. The legs must be firmly strained against the string loops.

TRITELEIA. Also called spring star Hower, this is a hardy bulb which blooms in spring. It will Hourish in sunny or shady places in ordinary soil. The chief kind is Tritcleia uniflora, which grows 6 in. high and bears white Howcrs, shaded with purplish bluc, in April. It is suitable for the rock garden and for planting in grass among trees; bulbs may also be potted in autumn and grown in the greenhouse. See illus. below

TRITONIA. These are hardy bulbs which bear flowers similar to those of the montbretia They should be planted in autumn in wcll drained soil in a sunny sheltered horder, as for instance at the foot of a house wall, where they will Hower in early summer. The chief kind is Tritonia crocata, of which varieties of brilliant colours have been raised. One of the finest is the orange-yellow I'rince of Orange. Other species of tritonia are generally included in montbretia (q.v.)

TRIVET. In the ordinary domestic sense a trivet is a movable iron frame cither fixed to the bars of a grate or supported on three legs and used for holding the kettle when it is oll the fire. Gas and clectric fires arc sometimes fitted with a trivet attachment for boiling a kettlc.

TROLLIUS. This is the botanical name of globe flower, a very showy hardy spring and early summer blooming plant especially suitable for the sharly border or for moist soil by the garden pool. The plants grow from 12 to 24 inches high and bear large, globeshaped blooms in various shades of orange and vellow. They should be planted in autumn in deep moist soil. Trollius europaeus, lemon yellow, and asiaticus and Ledebourii, golden yellow, are the chief species, but many beautiful varieties have been raised and these are now chiefly grown. A few of the best are Orange Globe, Empire Day and Fire Globe.

TROPAEOLUM. These are hardy or half hardy perennials and annuals, some being of great beanty. The loveliest of all is the Chilian flane flower (speciosum). a slende

Triteleia. Charming effect of this white spring star flower at the base of rocks. See article above
twining plant with graceful leaves and bearing a profusion of scarlet Howers in late summer. It attains its greatest beauty in gardens in Scotland and the north of England where the cool moist air suits it perfectly. In southern gardens it must be planted on the north side of a hedge, shrub or trellis in leafy soil : its light green foliage and brilliant llowers look especially well if allowed to trail over holly or other evergreen trees. The stems die down in autumn. Roots should be planted in spring about 4 in. deep.
The Canary creeper (Tropaeolum aduncum) is a popular half-hardy climbing plant with
yellow flowers in summer: it is raised from seeds sown under glass in March, the seedlings being planted out of doors in May. The common climbing nasturtium is Tropaenlum majus. Tropaeolum polyphyllum is a hardy perennial of low growth with grey leaves and yellow Howers: it should be planted in a sunny place in the rock garden and given some protection in winter. The scarlet flowered Lobbianum is a popular annual for pots in the grcenhousc. See Nasturtium.
TROUGH. Employed for holding various kinds of food for animals and poultry, troughs are made of wood, iron, stone, and cement. The simplest form is made of two boards nailed together in the form of a $V$ at an angle of $60^{\circ}$ or so with two ends of square wood. It can be used in thin wood for chickens, in thicker wood and to a larger size for rabbita and fowls, and in hardwood for pigs.

The usual type of trough for fowls, ducks, geese and turkeys is made from galvanized iron with wire guards and is obtainable in two sizes, 18 in . long and 6 in . wide and 24 in . long and 7 in . wide. The advantage of the guarded trough lics in the fact that the food cannot be trampled on and therefore it effects a saving of food. See Pig.

TROUSER PRESS. This is an appliance for pressing the creases in trousers. Some are provided with an extension to which the trousers are attached for the purpose of stretching as well as pressing them, in order to remove any bagginess at the knees.

Trouser presses are obtainable in several sizes, from those suitable for placing in a suit casc to those large and heavy enough to take several pairs of trousers. They are generally made in polished hardwood, with plated fittings.

A press can be constructed quite inexpensively. The plated fittings can be purchased for three or four shillings, and also moulded oak boards for the top of the press. The hase may be made of $\frac{1}{2}$-in. plywood. A stretcher attachment can be added if lesired.

In use the press is opened out, the trousers carefully folded and placed, on the botton board, and the top placed in position. The screws nearest the hottoms of the trousers are acrewed down first ; the top of the trousers is stretched, being held in position by the fingers while the sccond set of screws is tightened. If the press has a stretching attachment the top is removed and the top bar of the stretcher is folded back. The trousers are placed in position, the top replaced and tightened at the hottom, and the top bar of the stretcher placed over the cloth and screwed down tightly. The projection is folded back underneatl the bottom board and the top screws tiglitened up.
The method is the same when two or more trousers are placed in the press, but pieces of

Trouser Press. Compact press for several pairs of trousers. It is not too beavy to pack in a travelling trunk
stout cardboard or thin plywond must be provided to place between cach pair. When placing trousers with the permanent turn-up botton in the press, this portion of the trousers must be left outside, otherwise it is impossible to obtain a long crease.

TROUSSEAU. The trousseau or outfit of a bride is usually supplied by her parents, the amount spent upon it varying according to circumstances.

Fashions change so quickly that the old idea of the outlit which lasted for ycars has been modified considerably. A trousseau anerely contains as adequate and charming a collection of dresses, wraps, underwear and dress accessorics for the immediate scason as can be afforded.

Extra monev which the parents can give for the purpose is more useful in the form of a cheque for later spending than in buying up an excess of clothing which cannot be given reasonable wear before it is oll-fashioned.

The girl who is clever at needlework can make delightful additions to her trousseau at small cost. Dainty embroidery and handwork add greatly to the charm of lingerie, and are well worth the time and trouble they demand, as these things are expensive to buy when ready-made in beautiful stylcs and qualities Underwear should be marked with the bride's Christian name or initials and her new surname This marking can be done in ink, or the letters may be embroidercd. See Wedding.

TROUT. Anongst the various species of trout the river fish is most highly esteemed for its delicate flavour. It is in season from March to Septomber. When buying this fish, care should be taken to select one with bright eyes, red gills, and firm flesh, and it should be cooked as soon as possible after purchase. There are various methods of cooking trout, the larger fish being prepared much in the same manner as salmon.

Baking Trout. Baking is a favourite way of preparing trout. Clean 3 small fish, split them open and take out the bones; then lay them with the skin side uppermost on 3 thin rashers of fat bacon placed at the bottom of a lireproof baking dish. Season them to taste. Sprinkle a little chopped parsley and some lemon-juice over them, cover them with a greased paper, and then bake them in a moderately hot oven for about 20 min .

Frying Trout. To fry trout, clean the fish, split it and remove the bone as directed in the previous recipe, then sprinkle it with scasoned Hour, brush it over with beaten egg, and coat it with brealcrumbs. Fry it in a pan of smoking hot fat, and when browned on both sides, Irain and lift on to a hot dish. Fried parsley is the most suitable garnish, and mayonnaise sauce can be scrved separately.

Broiling Trout. Trout may also be broiled. To do this, first clean and split open the fish and take out the bone Season it to taste with salt and caycune sprinkle it with lemon juice, and then brush it all over with melted butter. Broil it before a clear fire for ahout 8 min . and serve with parsley sauce.
To boil trout, the fish, after cleaning, is put into a pan of boil ing water to which a little vinegar and salt have been added About one teaspoonfn each of vinegar and salt are needed to every pint of water. 'Take the scum from the top as it rises. The time
required for boiling depends upon the size of the fish, one weighing ' lb . needing about 15 min . When ready, Irain it and serve with shrimp sauce. Cut lemon makes a suitable garnish. See Fish; Salmon; Sauce.
TROWEL. Various patterns of trowel are used in building by bricklayers and plasterers, and small trowels of a different shape are uscful to the gardener. See Brick Casting; Cement: Plaster: Pointing: Ren dering; Tool.

TROY WEIGHT. This weight is employed for weighing gold, silver, diaınonds, and precious stones generally. It is as follows: 24 grains $=1$ pennyweight (dwt.), 20 pennyweights $=1$ ounce (oz.), 12 ounces $=$ 1 pound (lb.). The pound troy is not the same as the pound avoirdupois, as it only contains 5,760 grains against 7,000 .

TRUFFLE. The trulle is really an edible fungus which is found just below the surface of the ground in wooded districts and in forcsts on the Continent, some parts of France being famous for truffles. They are also obtained in limited numbers in England, but these are usually found to lack the par ticular flavour of the continental varicties.

In colour, truffics are red, white, or black. The black ones are the ripest and the most commonly seen, and are used to Havour sauces and stews and also sometimes scrved as a dish by themselves. They are very expensive, whether bought by the pound or in bottles, and are in season in October, Novem ber, December and January.
Bot tled truffics need no preparation before they are cooked, but fresh ones nced to be soalied in cold water for an hour or more to remove any particles of carth that still adhere. They should then be washed in several cold waters, brushed well, dricd, and peelcd and cut into shapes. The pecl may be used for flavouring purposes and should on no account be thrown away.
If served alone, truffles should be left whole, each one wrapped in a piece of buttered paper and then baked for about an hour in a hot oven. They are sometimes stewed in champagne, flavoured with vegetables and herbs. When used as a garnish, truffles are first boiled for about 15 min . They may be cut up either before or after boiling, according to taste.
Truffle Sauce. Clean a dozen truffles, cut them into thin rounds, and then stir them in a frying-pan over the fire, with a lump of butter slightly larger than a hen's egg, 2 dessertspoonfals. each finely chopped parsley and shallot, and scasoning to taste. After about 10 min . cooking, drain ofl some of the fat addl a little more fresh butter, $\frac{1}{2}$ gill gravy, the strained juice of $\frac{1}{2}$ a lemon, and a dust of cayenne. Continue stirring the saucc mintil boils and then scrve it immediately.

TRUG. A convenicnt type of basket for gathering vegetables and llower sprays is that known as a trug or Sussex trug. It is a wooden arm basknt with rounded bottom, and in length is about thrce times its width. It is largely employed for garden purposes in most country districts.
TRUMPET FLOWER. This vigorous, climbing plant, 18 ft . or more in height, bears tubc-shaped llowers in summer. Only two are suitable for cultivation out of doors and they must be planted against a sunny wall Teconra grandiflora and T. radicans, both with reddish-orange flowers. In mild districts they form admirable wall plants. They should be planted in autumn or spring in deeply-dug soil with which old turf and de cayed manure have been mixed. The side shoots should be pruned in spring. For a heated glasshouse two of the best kinds of trumpet flower are capensis and jasminoides.

TRUMPET LILY. This name is usually given to the familiar white flowered Lilium longiflorum, often called Easter lily becausc it is forced into bloom in large numbers for decorative purposes at that season. It is more useful for cultivation in pots under glass than for planting out of doors, where it does not usually Hourish for more than one or two seasons. Bulbs should be potted in autumn or winter, singly in 5 -in. pots placed in a frost-proof frame or greenhouse, and covered with fibre until they are well rooted. They should then be set in a light position in a heated greenhouse wherc they will make quick progress. The bulbs must be set low down in the pots to allow of a top-dressing of soil when roots form at the base of the stems. See Lily.

TRUNK. This word is used for a box made to carry luggage. A useful type is that known as the cabin trunk. The essential fcature of this is a lack of height, which en ables it to be stored away in a cabin. A serviceable size is 36 in . by 20 in ., with a height of 12 in ., but they are sold in larger and in smaller sizes.

Onc variety of cabin trunk has a frame of three-ply wood covered with brown canvas. It is strengthened by wooden hoops and is. fastened by two locks. A tray that can be lifted out is the only internal fitting. A better type has a fibre foundation and the corners are protected by stout pieces of leather.
Wardrole trunks are bulky, but their fittings and compartments make them easy to pack and unpack. It is not advisable to buy large trunks in cheap qualities.
So much confusion arises when trunks of similar appearance are unmarked, or when the labels are torn off, that it is always wise for the owner to have his or her initials painted on in a conspicuous place. This will help to avoid loss or delay. See Holiday; Lock; Lost Property ; Packing ; Suit Case.

TRUSS. By the term truss is generally meant an apparatus usually composed of a leather-covered spring and a pad used in the treatment of hernia or rupture. Its object is to prevent the hernia from slipping out after t has been reduced.

A truss should be worn continuously while the pationt is in the upright position. While in bed it may be discarded, unless the patient suffers from a cough. The whole virtue of a truss lies in its being correctly fitted and adjusterl. In young children the complete cure of rupture may sometimes be looked for if a correctly fitting truss is worn constantly for two or three years. In children in their eens, and adults up to well past middle life, a complete cure by operation is nearly alwavs preferable to the wearing of a truss. See Piles; Rupture.

TRUSTEE: His Duties. When one person holds property of any kind for the benefit of another or others he is said to be a trustee, and to hold the property upon trust for the beneficiary or beneficiaries, who are also called cestui qui trustent. A trust may ba created by will, deed, or other writing, or even by word of mouth; but it must be evidenced by writing if it relates to land or other hereditaments.

If a trustee dies or becomes incapable of acting or desires to be discharged, refuses or is unfit to act, or remains out of the United Kinglom for more than 12 months, then a new trustee may bc appointed. If the instrument creating the trust gives to anybody the power of appointing new trustees, that person makes the appointment; but if there is no such person then the surviving or continuing trustees or trustee or the executor or administrator of the last surviving or continuing trustee appoints the new trustees or trustee

If there are more than two trustees, and one of them dies or retires, it is not necessary
to appoint another in his place so long as there are two left; but if there are only two. then one cannot retire without another being appointed to replace him. If a trustce mis. conducts himsclf, an action may be brought by any beneficiary or co-trustec to have him removed and another trustee appointed.
A trustee should only invest trust money in trustee securities, unless the trust deed or will gives him power to do otherwise. If he invests money on mortgage, he should have the land or houses valued by a competent surveyor, and not lend more than two-thirds of the valuation. A trustee is liable personally for breaches of trust; but he may apply to the court to be protected should he have acted honestly though
 mistakenly.
A trustee ought not to carry on a business co-trustee should never allow the other counless the trust deed or will gives him power trustec to administer the trust without to do so. Suppose the testator who created constant checking. It is his duty, if he allows the trust left the whole of the property to his co-trustce to receive trust money, to take trustees in trust for his widow and children, care that it is properly invested or otherwise and amongst the assets is a business, it is the trustees' duty to realize the business and invest the proceeds in trustee securitics, because it is for a trustce to look to safety rather than to high interest. In some cases, however, the will or deed gives trustecs wide power of investment, and then they are safe so long as they keep within the four corners of the instrument. If a beneticiary tries to persuade a trustce to make an unauthorized investment, the trustec should always take from him a letter requesting such investment to be made, and giving an indemnity against the consequences.

Trustee Investments. The sort of investments allowed by the law are the following : British Lovernment securities; Bank of England stock; Indian Government stock; Metropolitan stock; Metropolitan Water Board stock; British railway debentures or preference stock, if the railway for 10 years has paid 3 per cent dividend on its ordinary stock; guaranteed Indian railway debentures; British water companies incorporated by royal charter or special Act of Parliament, where the company has paid 5 per cent on ordinary stock for the past 10 years ; municipal borough or city corporation stock, where the place has a population exceeding 50,000 ; mort. gage of real property up to two-thirds value : any security for the time being authorized by the high court.

Breaches of Trust. When trust property has been improperly disposed of, the beneficiaries are entitled to follow it as long as it can be traced and identified. If a trustee mixes trust money with his own, as by paying it into his own account at his bank, the beneficiaries are entitled to be paid out of that account in priority to anybody else: because it is always assumed that any money which he drew out for his own purposes was his own money and not trust money, and therefore all that is left is trust money.

Where there are co-trustees, each one is liable to see that the funds are properly taken
care of and cluly administered. Therefore, a

## disposed of at once

If he is informed that the money has been invested on certain securities, he should demand to sec those securitics; and he ought to take care that all trustccs' securities, such as mortgages and stock certificates, are made out in the joint names, and are deposited in the joint names at some bank or other place of equal safety.

If a trustee is found guilty of a breach of trust, and is ordered by the court to make good the money which he has lost, the beneficiaries can compel any one or more of the trustees to make good the loss; but the one who has in fact nuade it good can sue the other or others for their share. If a breach of trust has been committed at the instigation of a beneficiary, and the trustce is ordered to make it good to the trust estate, the court will also order the beneficiary in question to indemnify the trustee out of his share of the trust funds.

Trusts are very often family affairs, and it is sometimes inconvenient to administer them on strict lines; but a trustee who departs from the straight path, even with the best intentions, may find himself landed with heavy liabilities. as a consequence of his mishandling of trust funds. The iollowing fase, although an hy pothetical one, may scrue as an example.

Suppose, for example, a man left all his estatc to trustees upon trust to pay the income to his wife for life, and after her death to divide the capital amongst his children. It may be that the estate is a very small one, and that upon some emergency the widow's income does not suffice for her needs, and she asks that a portion of the capital shall be handed to her or used for the benefit of herself or one of the children. If all the children are of full age, the trustee will be safe if he procures them alk to sign a letter requesting him to make the payment which their mother requests; otherwise he is running a risk.

A trustee is not allowed to use money for his own purposes out of the trust money, or to make any profit out of his trusteeship,
unless expressly permitted to do so by the trust deed. It sometimes happens that where money is invested at low interest in goverument securities a trustee will say, Let me use the money in iny business and I will pay $7 \frac{1}{2}$ per cent. If he docs use the money in his business, and makes a prolit out of it of more than $7 \frac{1}{2}$ per cent he can be compelled to hand over every penny of that profit. On the other hand, should he lose the money, he is liable to pay the whole of it back with 5 per cent interest.

When a trustee is in doubt as to the proper course to take, especially where the will or deed is of doubtful construction. his best course is to apply to the court. Anybody interested in the trust has a similar right to apply to the court on doubtful points. See Executor; Guardian; Ward.

TRY SQUARE. This is a carpenter's tool employed for testing the accuracy of rightangles. As can be seen from the accompanying illusitration, it consists of a tlat parallel-sidel steel blade attached to a stock made of a parallelsided piece of hardwool. The working edge of the stock is faced with a strip of brass, the angle between the face of the brass and the inner edge of the steel blade being exactly $90^{\circ}$.

In a well-made square the outer edges should be at right angles, and when the square is placed on a level surface in a vertical position, the blade should be at right angles to the level surface.

## T SQUARE.

 parallel lines, usually comıprises a long blade of mahogany or other wood and a stock made of thicker wood. The working edges of the blade and the stock should be at right angles to one another, the blade and the stock being firmly united by dowel pins and screws. Its most extensive application is in the preparation of drawings, when the $T$ square is used in conjunction with a drawing hoard. It should be slightly longer than the board. Probably the most serviceable pattern is a mahogany i' square about 30 in . long. A common type is made in pearwood. The usual practice is to have the left hand
edge of the drawing board smonth and true, and to worls the T' square from this edge. The mode of operation is illustrated in ligs. 1 and 2. See Drawing; Set Square.
TUB. Tubs are employed for various domestic purposes. In former days they were much used for washing, and the dolly tub, as it is still called, is sometimes scen today. Another use is for holding

Testing a joint lor prightness advantage.
water. must be bored in the bottom for drainage and crock (pieces of broken flower-pot) placed over them. It is necessary to use loamy (turfy) soil for the bulk of the compost; a little decayed manure may be mixed in with

Some of the best flowering plants for tubs are hydrangea, bluc African lily (Agapanthus umbellatus), plantain lily (funkia), fuchsia, lemon-scented verbena, myrtle and rosemary. The myrtle, verbena, hydrangea, fuchsia and agapanthus should be kept in a frost-proof place for the winter. Suitable evergreen shrubs are holly, box, bay laurel, retinospora, rhododendron, skimmia and lanrustinus. Roses too may be rown in tubs. of a plant, stored with starchy food, which gives nourishment to the young buds or cyes which it bears at intervals, until they are strong enough to obtain nourishment direct from the soil. When a stock of plants is increased by separating the tubers, as in the case of potatocs or dahlias, the resulting crop is always true to type. See Artichoke: Begonia; Dahlia; Gloxinia; Nasturtium; Potato, etc.

TUBERCULOSIS. This disease is characterized by the development of small nodules called tubercles, which are due to the presence and activity of
plants that serve to ornamay also be let into the ground and used to hold

Tub Plants. Many attractive shrubs and plants can be grown in tubs; they look particularly well on terraces, on cither side of garden steps, in paved courts, by the side of doorways and are admirable in town and roof gardens. Tubs made of teali are particularly to be recommended because they remain sound indelinitely, but they are expensive. T'ubs of oali and other wood are also used; they are usually painted dark green. Holes

TUBER. In gardening a tuber is the saliva, or using his food utensils which have TUBER. In gardening a tuber is the saliva, or using his food utensils which have
swelling or underground expansion of the stem not been properly cleaned, may convey the the tubercle bacillus. The commonest means of entrance of the bacillus into the system are by inhalation. the patient breathing in the germ ; by inocula. tion. the germinding its way through a
broken surface in the skin or mucous membrane ; and by means of food or drink infected by the germ. Milk and meat are the commonest articles of diet which are likely to be contaminated by the tubercle bacillus.
lersons crowded together in the poorer districts of cities are naturally nore liable to contract the disease than those who live in the country and get plenty of fresh air and sunshine. Thin, llat-chested persons account for many victims, but the discase is by no means uncommon in the well developed. Indoor workers, particularly in dusty trades, such as stone cutters, miners, mill hands, and factory hands in general, are all more than normally open to the disease.

Those who live in close association with people suffering from the disease run great risks unless care is taken to use a sputum tlask and disinfect the sputum, in which the real danger lies. If this is allowed to be disposed of about a room it dries up, and the dust of the room becomes impregnated with it. Using a book the pages of which have been turned over by a consumptive moistening his finger with
 Tuber. 1. Of flame nasturtium, 2. Ranunculus. 3. Peony. 4. Madeira vine. 5. Richardia. 6. Incarvillea. 7. Potato. 8. Wax lountain flower infection. Infants fed on milk from tuberculous cows are liable to incur infection of the glands of the bowels, whence the disease may spread to other parts. Children convalescing from meas!es and whooping cough often lall victims to the disease.
Tuberculosis attacks certain parts of the body seemingly by preference, but practically no part is exempt. The most common site is the lungs, the discase in that case being known as consumption. Tuberculosis also attacks the bones and joints, the intestines, lymph glands, kidneys, peritoneum, bladder, and the brain, heart, spleen, and generative organs.

In the treatinent of tuberculosis in general, sunshine, fresh air, and a gencrous diet, including plenty of fat and especially cod liver oil, play a very important and indispensable part. Specilic treatment in the shape of injections of tuberculin are of the utmost use in some cases.
The Disease in Poultry. This is one of the most common diseases of fowls and other birds. Affected fowls become anaemic, thin, listless, cmaciated and lose weight. The comb and wattles become pale, and in the later stages there is usually persistent diarrhoea. When this sets in, the appetite, which was good in the earlier stages, becomes impaired and feeding is very erratic.
As a consequence of extreme emaciation, which is a noticeable symptom, the bones become very prominent. The joints of the foot,
knee, or shoulder are somotimes affected and slowly become enlarged and painful, causing lameness or drooping of the affected wing, according to the position of the lesion. The onset of diarrhoea is followed by exhaustion and death. These facts are taken from Leaflut No. 78 issued by the Ministry of Agriculture.

Hoalthy birds become infected with tuber culosis by eating food or drinking water which has been contaminated by the droppings of infected birds. Damp, dirt, and absence of syunlight greatly favour the spread of the disease; good ventilation and strict cleanliness in the runs and sheds assist against, though they do not prevent, its spread.
All diseased birds should be killed and buricd in lime or burnt; the poultry house should receive several thorough applications of disinfectant, and the tainted run should be heavily dressed with quicklime and dug over. Several months should elapse before birds are put back into old quarters that have been cleansed and disinfected.

Where the discase breaks out, it is best to clear off old stock and make a fresh start with new stock later. Attempts to dea! with diseased birds only with a view to saving part of the stock are almost certain to lead to dis. appointment, and new cases among birds in the Hock will cone to light from time to time. When the premises have been thoroughly disinfected, the new stock'should be carefully selected from strong, healthy birds, which should not be brought on whilst any part of the original stock remains. If this is impracticable, the old and the new stock should be carefully separated from each other.
The disease, in exceptional cases, may be transmitted from affected birds through the eggs to the chicks, though the latter may not show symptoms until they arc fairly well grown. It is advisable, therefore, not to use any eggs for hatching which have been de rived from fowls amongst which tuberculosis is known or suspected to exist. See Consumption; Curvature; Gland; Light; Lupus.

TUBEROSE. This is a pretty and pop ular half-hardy tuberous plant, with white fragrant flowers; the double forms enjoy the greatest favour. Pearl is one of the best varicties. The botanical name of the tuberose is Polyanthes tuberosa.

The tuberose is grown from imported bulbs, which are best potted singly in 4 in . or 5 in . pots, in a compost of loam with a third of decayed manure or leaf-mould and a liberal admixture of sand. Leave the upper part of the tuber exposed. Stand the pots in a frame or cool greenhouse, and give very little water for two or three weeks: then put them in a warm house in successional batches and kenp the soil moist. This will ensure a long supply of bloom.
The flowers are charming for wreaths, buttonholes and bouquats. It is not worth while to keep the tubers after Howering, and fresh supplies should be procured annually.

TUBING. Flexible metallic tubing is largely employed for connecting gas rings or gas table lanps where portability is desired. The best method of cutting this tubing is to file a slot along one of the spirals until it is thin enough to break off. A three-square tile is suitable for the purpose, but a hack saw may be used. The brass and copper tube used for gas is dealt with in the article on Pipe. Other information will be found in the articles on Brass and Copper.

Rubber or canvas tubing is much employed for garden watering or washing down the concrete Hoors of garages or outbuildings. It is dealt with in the article Hose Pipe. See Barrel; Gas.
TUCK: How to Make. A stitched fold takom up double in the material and arranged to lie over single material constitutes a tuck.

They are made on the right side of the fabric, and vary in widt
arranged in groups.

The distances allowed between the tucks is very much a matter of taste. Narrow tucks may almost touch each other, or the space apart may be the tuck's width; where the tucks are very wide the distance between may he less than their width. Unless the tucks are being made in a garment cut from a paper pattern, on which both the tucks and spaces would be marked, it is a good plan to experiment with a piece of paper till a satisfactory offect is gained.
The narrowest tucks are termed pin tucks. As these only necessitate the taking up of a few threads of material in each a group will not seriously effect the length or Tuck. Showing the use of a cardboard (h) of a garment, but for gauge to ensure evenness of the tucks wider tucks extra material
 must be allowed. For instance, a tuck that is to be $\frac{3}{\frac{3}{4}}$ in. wide when finished will take up $\frac{3}{3}$ in. of material, and lie over ${ }_{R}^{3}$ in., i.e. the tuck width.
In making tucks the great point is that they must be straight whatever the width. For a pin tuck it is sufficient, at the position needed,

## Tudor Style in House and Furnishing

## Models which Influence Design and Craftsmanship To-day

## This article belongs to the group in our work dealing with British period styles in building, decoration, and furnishing. Other entrics containing information on Tudor style are Chimney; Door ; Fireplace; House; Linenfold; Panelling; Settle; Sideboard; Silver W'are; Stained Glass; Staircase. See also Jacobean Style

Althoug! the Tudor style in architecture is added as the rich influence of the Renatissance described as transitional between the Gothic spread during the latter reign. and Renaissance, it possessed marked features. Throughout the 16 th century there occurred which resulted in a blend that was cssentially in England a remarkable development in English and culminated in the erection of clomestic architecture, made possible by the many beaut iful buildings including such famous increased security that followed the abatement clwellings as Hampton Court, St. James's of the civil wars. Manor houses were built Palice, and Haddon Hall. instead of moated and fortified dwellings and Nominally including the years between town planning was carried out 485 and 1603 it found its chief national ex- Early Tudor houses, cven the important pression during the reigns of Henry VIII and ones, show little orderliness either of elevaElizabetb. flanking towers in the larger oncs, lean-to roofs in the sma!ler farmhouse type, very substantial chimney stacks, hcautiful stonework around doors and windows, cusped window heads showing trefoil and quatrefoil formations, the Tudor arch, and the half-timbered walls to be found on many, are all features which make them attractive.

One way to distinguish carly from late Tudor is by the windows. In the former there is only nne row of lights, and these are quite small, though probably large enough for the height of the rooms they served. The reluctancc to have large windows in outside walls still lingered, a relic of the tradition that a house should show as few vulnerable points as possible to hostile missiles from outside. Also glazing was not in general use and glass was cxpensive. As late as 1573 it is recorded that the windows of a country mansion belonging to the duke of Northumberland were carefully stored during his nbsence in London for fear the precious glass should be broken, and other similar cases are on record.

Later the window space was enlarged, transoms or crosshars were intronuced, and windows were brought into conformity with the loftier ceilings and larger apartments generally that were characteristic of the end of the 16 th century.

Tudor designers always made a feature of their chimneys. The method was to group two or three fireplaces together, as is done nowadays, but the flues were carrice up the great stonc or hrickwork stack in single shafts, which were often surmounted by handsome caps. In the reign of Henry VIII chimneys were often twisted and counter-twisted; they were wreathed with spiral bands of stone or brick, or the shafts were intricately panelled. This characteristic feature is revived in moderation and adapled to-day by architects for suitable houses. Some cxamples are shown in page 230 as illustrations to the article on Chimney.

The arched window disappeared in farour of the square-headed one, and in important houses classic pilasters were used to frame the mullioned windows: a complete entablature at every Hoor level made the circuit of the

Tudor Stgle. Fig 2. Double seated bench or settle in oak. The carved motifs in the panelled back and the frieze of the seat show designs in low relief characteristic of the period
Bu Dermission of the Dircetor. Victoria \& Albert Museum
building instead of the plain string course, and the gables were frequently linked together by a balustraded parapet, all in obedience to the new fecling for orderly design in the Renaissance manner.

The various wings of the larger Tudor houses were, as a rule, ouly one room wide, which meant that some of the rooms hiad to be thoroughfare rooms; a very incouvenient arrangement in modern eyes. Then the typical staircase of the Tudor house was of the corkscrew type; a straight flight in the thickness of a wall was its alternative.

One feature, however, of !ater Tudor architecture, viz., the bay window, readily adapts itself to modern building, and even the overhanging oriel window can be copied with charming effect where the design admits of something of this kind.

It is probably truc that a larger proportion of country and suburban houses built during the latter years of and since the end of the 19th century are based on the Tudor model than on any other period style. They are only beautiful when designs are modified and adapted by highly skilled architects, who avoid superficial imitations which have cither lost significance in modern surroundings or are out of kecping with the size of the house, but bring into the scheme the essential features evolved to suit an English background. The builders and craftsmen of the Tudor period used the materials close at hand. Thus in the Cotswold district and in Somerset 16 th century houses are mainly of stone, while in Surrey, Sussex, and Kent they are half-timbered, oaliframed, the pancls between the timbers being filled in with wattle and dnub, both inside and out, and washed with buff or whitc.

Interior Decoration and Furniture. Excepting the halls of the larger mansions, or manor houses, rooms of the earlier Tudor period were low built, while doors and fireplaces show the flat arched openings of the shape known to-day as the Tudor arch. Linenfold panelling was replaced in the houses of the rich by more decorated styles and as rooms were built higher in the larger houses, ceilings were also intricately and lavishly decorated. Colour was of ten introduced into their plaster work modelled in floral and heraldic designs.

An example of a beautiful Elizabethan room, reconstruc. ted in the Victoria and Albert Museum, is shown in Fig. 1. The panelling was removed from the room known as the "inlaid room" at Sizergh Castle, Westmorland, and the frieze and ceiling are reproductions in plaster from the originals sti!l at Sizergh Castle. The ceiling is enriched with pendant ornaments from which spring ribs forming compartments with foral designs, medallions of goats. chained stags and shie!ds of arms. The plaster frieze has a repeating floral pattern with demi-figures. The panelling is of oak inlaid in holly and bog oak. The upper portion has a row of arcades, while the lower portion or dado is divided into panels by mouldings. There are three horizontal bands of geometrical inlay.

In Tudor days colour was lavishly used in strong, bold tones ; reds, greens, and white were most gencral. Besides inlay, gilded and coloured wood and plaster enrichments, ta pestry (mostly imported) and

Tudor Style. Fig. 3. Oak cabinet, 4 feet high on a atand with legs united by square stretchers. panela shows the popular arcaded formation Victoria ، Albert Museum
painted canvas or tapestry needlework hangings were employed as wall coverings. Stained glass was introluced into the windows by wealthy houscholders. Chimnfy pieces were massively decorated above the fireplaces with coloured and gilded ornamentations in stone, plaster, and woodwork. Floors were of wood blocks, of clm planks and of brick or stone.
Carpets began to be imported from the East. They were smal! in size in romparison to the rooms, as may be seen in Fig. l, but made up for this in richness of colour. Delicate tones are out of place in any Tudor decorative scheme, and the same may be said of limsy materials. Velvet, linen (plain or embroidered) heavy satin and damask were the textile fabrics used.

The pieces of furniture, though still scanty, increased in variety in late Tudor times. In Fig. 1, the forcrunner of the gate-lcg table is seen on the right, and a carved oak side table on the left, while the beautiful chair, the chest and also the tester and headboard of the bed are decorated with inlay and carving.

The oak settle illustrated in Fig. 2, has the panelled back with carved motifs frequently seen on later Tudor pieces of the less costly type. Strapwork and guilloche decoration was also much used on thesc. Renaissance ornament consisted of classical heads in medallions, dolphin-headed scrolls, vases and floral forms. Fine carving in this style was done on seats, court cupboards, and chests designed for great houses.

Earlier furniture was more austere. It was often carved with linenfold, horizontal, and vertical and the pieces were simple in shape. The oak cabinet illustrated in Fig. 3 has inspired the shape of countless cabinets in different styles of decoration and in different woods which have been constructed through intervening periods, and still find places in modern rooms.

TULIP. This is the most brilliantly scarlet; Kaufmancoloured of spring and early summer flowers and unsurpassed for providing an attractive display in beds and borders. The two chief types are the early or April Howering tulips and the May flowering tulips, which consist of Darwin and Cottage varicties.

The tulips which bloom in April are great favourites for planting in spring flower beds, where they provide sheets of glowing colour. The bulbs should be set 3 in . deep and about 7 in . apart in October; as the soil is dug, some thoroughly decayed manure and a sprinkling of bone meal should be added. If the soil is clayey it is a good plan to add sand. Some of the finest varieties are Artus, bright red; Chrysolora, yellow; Cottage Maid, rose and white; Coulcur Cardinal, crimsonscarlet; Primrose Queen, pale yellow; Prince of Austria, orange buff. fragrant; Queen of the Netherlands, pink; White Swan, white, and Yellow Prince, yellow, fragrant.
The double tulips which bloom in April have large and handsome flowers. Couronne d'Or, orange yellow; El Torcador, red and yellow; Imperator rubrorum, red: Murillo, pale rose; and Vuurbaak, scarlet, are some of the best. The A pril fowering tulips are about 12 in . high when in bloom.
The May tulips are magnificent flowers the large, handsome bloonis are on stems from 20 to 30 in . high. The bulbs should be set early in November, 5 in. deep on heavy soil, 6 in . deep on light soil, and about 10 in . apart. In association with Siberian wall. flower and forget-me-not they provide many brilliant colour schemes.

Most of the Darwin tulips have immense cup-shaped blooms, those of the cottage tulips are chiefly long and pointed. A few of the finest Darwin tulips are Antony Roozen, rose; Bartigon, red; Clara Butt, pink; Europe, rose red; Farncombe Sanders, red; La Tulipe Noire, almost black; Pride of Haarlem carminc ; Rev. H. Ewbank lavender; The Bishop, palc purple, and Zwanenburg white.

These are beautiful cot tage tulips: Amber Crown, amber-rose; Bouton d'Or, yellow; Carrara, white; Dom Pedro, maroon and brown; gesneriana lutea, yellow; gesncriana spathu lata, deep red; Golden Crown, orange-red and yellow ; Inglescombe Pink, rose pink; La Merveille rose and buff; Moonlight pale yellow; Mrs. Moon yellow; Walter T. Ware golden yellow.

The parrot tulips arc striking flowers of brilliant colouring with deeply cut petals. They bloom in May: the stemsare weak and must be supported or the Howers will be spoilt. The old English tulips, which are classified as bizarres, byblocmens and roses, according to their colours, are rarely grown nowadays, except by connoisseurs and exhibitors. The flowers of the Rembrandt tulips, which open in May, are blotched and striped with various colours. Three new types of tulip are the lily-flowered with reflexed petals, which are in full bloom in May: Mendel, specially adapted for cultivation in pots under glass, and the Triumph tulips, which are intermediate between the April and the May flowering varicties.

Some of the wild species of tulip are very beautiful and suitable for planting in the rock garden. Clusiana, red and white; Greigii,

Tulip. Beautifully shaped pink blooms of the Inglescombe variety, suitable for outdoor plant-
ing. Above, vivid flowers of the parrot tulip in a large number of shades, R. Above, Divid Aowera or the parch tulp niana, cream; linifolia, scarlet, and persica,bronzeyellow, are particularly attractive.
The Duc Van Thol tulips, which bear small red, pale rose or yellow blooms, are useful for forcing: if potted in AugustSeptember and grown under glass they will bloom in winter. Some of the April flowering tulips also do well in pots.

TULIP TREE. This is the common name of a North American leaf-losing tree (Liriodendron tulipifera), which is hardy in Great Britain. It belongs to the magnolia family, will reach a height of 60 ft . or more, and thrives best in loamy soil. The green and white flowers open in spring.
TULIPWOOD. This is a richly figured wood used in former days for inlaying and marquetry. It was used to decorate pieces of furniture made in the Adam and Louis styles, and was employed with much effect by the great French cabinet makers. See Inlaying; Louis Style ; Marquetry ; Wood.
TULLE. The thin gauze-like silk material which is known as tulle can be obtained

Tulip Culture. 1. Placing bulbs in pots or bowls. 2. Bowl culture: a, charcoal; $b$, fbre ; $c$, moss. 3. Stage at which light should be allowed. 4. Pot culture : $a$, crocks ; $b$, rough soil ; $c$, compost ; $d$, moss. 5. After planting : $a$, ashes; $b$, covering box ; $c$, glass. 6 . Correct outdoor planting $: a$, sand $i b$, fine soil. 7. Bad planting : $c$, glass. water accumulation ; $b$, lumps soil instead of fane compost
made in varicd qualitics. The best are of fine cut glass. They are usually sold in dozens or half-dozens, sometimes to match the rest of the table glass, and can be had in several sizes.

Antique tumblers may be valuable. They were made toward the end of the 17 th century by the great glassworker John Greene. These werc either plain or ribbed, horizontally or perpendicularly, or adorned with surface moulding, pressed, as it is called. They werc of different sizes, and many were originally arranged in nests, each nest containing 6 or 12 . For beer they were made in their present shape early in the l8th century, but good specimens are rare.

The best tumblers date from the middle of the 18 th century. These taper very slightly and are sometimes engraved with sprays of roses, with hops and barley, or with a vine pattern. Toward the end of the 18th century the tumbler became fairly common. Those seen in antique shops arc chiefly of the carly part of the 19th century. They include squat and heavy examples made of fine cut glass as well as the taller pattern, tapering considerably and cut nearly all over in a scries of indents. See Glass Ware; Rummer.

TUMOUR. In medicine the technical name for a growth is tumour, and there are two main groups, the simple and the malignant. A simple tumour, if it does damage, does so only by pressing on neighbouring structures. A malignant tumour, on the other hand, infiltrates and clestroys adjoining tissues, and at the same time its cells are carricd by the lymph or blood streams to distant parts, where they grow. Thus a cancer in the breast or in the stomach may lead to a secondary growth in the brain. Hollow tumours are given the name of cysts. They contain some kind of fluid. See Cancer.

TUNICA. These pretty little hardy plants belong to the pink family. The most attractive is Tunica saxifraga, 8 to 10 in . high, with slender stems and small, blush-coloured Howers in summer. It is suitable for the rock garden or for setting in the crevices of paved paths. Seeds may be sown in spring where the plants are to bloom in summer, or the seedlings can be raised under glass and transplanted.

TUNING: In Wireless Reception. This is the act of bringing the tuned circuit, or circuits, of a receiver into resonance with the wave-length of a broadcast transmitter.

Tuning is normally carried out by means of a variable condenser connected across an
inductance coil, and the circuit is said to be in resonance or tune when the condenser control is adjusted so as to give maximum volume.

A receiver will only give the best results when the wave-length to which its highfrequency circuit or circuits are adjusted is the same as that of the desired broadcast transmission. It is essential that the tuning circuits of a "ganged" receiver should be correctly matched, otherwise one of these circuits may be slightly out of tune when the others are in tune, thus producing a loss of efficiency and therefore diminution of volume. See Selectivity.

TUNING FORK. A tuning fork consists of a bar of steel bent into an elongated $U$. shape, with the prongs supported at the bend by a foot. When struck smartly upon a firm but not hard body it gives a musical note.

Owing to the fact that the tuning fork is practically invariable in its pitch, and that its tone is singularly pure, it is commonly used to indicate an exact standard of pitch. For ordinary use they are procurable generally for A or C .

TUNNY FISH. This is a fish of the mackerel tribe, and, like lax, it is preserved in oil. It is served as hors d'oeuvres, being cut into thin slices and having fresh oil poured over it.
A good savoury of tunny fish can be made in the following way: Prepare a thick white sauce, add to it some flaked tunny fish, and cook them over a slow fire until the fish is heated through. Then pour the mixture on to small rounds of hot buttered toast and serve at once. See Fish; Lax.

TURBOT : How to Cook. The finest of all flat fish, turbot is at its best from April to September. The flesh is firm and white, cuts

Turbot. Boiled turbot garnished with slices of lemon and some pargley from the middle and back being the thickest and considered the best.
Turbot can he cooked in many ways, but boiling is the most favoured method. To prepare the fish, first clean it, wash it in several waters, and then rab it with a piece of cut lemon to remove any discoloration of the skin. Do not cut off the fins. Turn the fish over so that the black skin is uppermost, and score this down the middle to prevent the white skin on the other side from breaking while the cooking is in progress. Then put it into a pan of boiling salted water or fish stock, laying it so that the white side of the skin is uppermost, and cook it gently until the Hesh begins to leare the bones. Keep the water or stock in which the fish is cooked well skimmed. Boiled turbot may be served with melted butter, shrimp, oyster, or hollandaise sauce.

To broil turbot, first season it to taste and lay it in a dish containing a gill of salad oil and half that quantity of lemon-juice. Then broil it in front of a clear fire, basting it frequently with the oil and lemon-juice and turning it several times. It may be served with oyster sauce and garnished with parsley.

Steamed turbot, coated with egg sauce, provides another good dish. To prepare it, clean the fish, place it in a steamer over boiling water, and steam it for $15-20 \mathrm{~min}$. If a stcamer is not available, stand the fish on a plate over a saucepan of boiling water and cover it with
a saucepan lid or a basin. If cooked in this way it will require a little more time. Pour the egg sauce over it on the dish and proceed to serve it at once.

Made-up Dishes. Remains of cold turbot may also be utilized in the following way: Melt a lump of butter about half the size of an egg in a small pan, stir in 1 dessertspoonful flour and when they are smoothly mixed add 1 teacupful milk, salt, pepper, and cayenne to taste, and $\frac{1}{2}$ teaspoonful anchovy essence. Keep stirring all the time, and when the last of these ingredients has been added, draw the pan to the side of the stove so that its contents may cool a little and stir in the yolk of an egg.

Pour a little of this sauce into a fireproof dish, then cover it with some cold cooked turbot that has been boned and broken up with a fork. Continue with these layers until all the ingredients are used, then sprinkle some browned breadcrumbs and grated cheese over the top and bake until it is heated through.

Reheated and served in the following way cold turbot makes an excellent luncheon dish. Peel a small onion, stick a few cloves into it, and put it into a saucepan with $\frac{1}{2}$ pint milk and 1 oz . butter. Let these stand at the side of the fire for an hour or so, so that the milk may become well flavoured, and in the meantime boil an egg for 15 min ., then shell it, cut it into halves, and take out the yolk. Cut the white into small pieces, rub the yolk through a fine sieve, and take the skin and bones from 6 oz . cold turbot, breaking the flesh into small flakes.

When the milk has stood for the required time, bring it to the boil, take out the onion and cloves, and sprinkle in half a tumblerful of breadcrumbs, the flaked fish, white of egg, and salt and cayenne to taste. Stir these well over gentle heat until they are well mixed and thoroughly hot, allowing time for the bread to cook; then add 2 tablespoonfuls cream and reheat the whole for a few minutes.

Turf and its uses in garden and greenhouse. 1. Stack for potting soil : $a$, tarves ; $b$, lajers of lime. 2. Marrow mound. 3. Turi as base for pot planta : $a$, ashes ; $b$, turf. 4. Dimensions for cutting. 5. As rooting medium for seedlings. $e^{e}$. Gentle hotbeds: $a$, ground soil ; $b$, turves ; $c$, manure

Serve it on a hot dish, garnished with lines of powdered parsley and the sieved yolk of egg. Cold turbot may also be curried, adding the Haked cold fish to a good curry sauce. Serve very hot with a border of freshly-boiled rice.
The roe of turbot should be blanched and sliced, baked in a buttered dish in a moderately hot oven, and basted frequently with the butter. It will need about 20 min . cooking. See Curry; Fish; Hollandaise Sauce; Sauce.
TUREEN. A tureen is a large dish or bowl, usually fitted with a lid. Either round or oval in shape, it is used for holding soup or sauce at the table. Tureens are often made to match a dinner service, and range, therefore, from pieces of the costliest china to those of the cheapest earthenware. They are also made in silver and Sheffield plate and some of the 18th-century specimens are of great value. See Ladle; Sauce Boat; Soup.
TURF. This is a term used to denote the top spit of meadow land, or a stretch of lawn. Lawns laid with turf become fit for use sooner than others made by sowing lawn grass seeds, but it is most important to lay turf which is free from weeds and coarse grass or it will cause endless labour. The chief details needing attention in the maintenance of a perfect stretch of turf in the garden are mowing, rolling, the destruction of weeds, and the use of fertilizers. If the top spit of meadow land is pared off in turves, about 4 in . thick, and stacked for a year, it becomes what the gardener calls turfy loam. If alternate layers of manure and turf are stacked the loam will be still more valuable. See Lawn.

## TURKEys: Rearing and Cooking

## Hints on the Treatment Needed to Produce Good Table Birds

The early part of this article is mainly for the benefit of country readers. The sections on preparing and cooking the bird will be of value to readers in all districts. The articles Duck; Fowl; Poultry ; also Casserole ; Forcemeat ; Stuffing, deal with related subjects. See Carving ; Christmas

The rearing of turkeys is best carried out on a large scale, one reason being that the abundance of natural food required by the birds necessitates extensive feeding grounds. They require, too, a good deal of care. Nevertheless, as smallholders and other persons with a little land may like to keep one or two, some information, from Leaflet 229 issued by the Ministry of Agriculture, is here given.

Although turkeys may be raised on heavy land, as a rule they do better on lighter soils, except in dry weather, when there may be a
deficiency of green food. The best results are obtained upon a rich soil which is not absolutely heavy in character. If a choicc of position is possible, preference should be given to a dry and sheltered one, facing south and protected from cold winds. Every advantage should be taken of banks, hedges, and belts of trees which will serve as windscreens.

The Best Breeds. The American Bronze is a popular breed of turkey, but the Cambridge Bronze is probably a better one for ordinary
keeping purposcs. On the average its males reach from 20 to 24 lh . and its females from 12 to 16 lb . They fatten up readily. For those who want a smaller bird the white turkey is recommended, while a cross between this and the Cambridge produces a hardy bird comparatively casy to rear.

Roosting. Adult turkeys should roost in the open all the year round. Special protection may be necessary to enable them to do this, but it is better thin placing the roosts under cover. Where large trees are available, the lirds may be allowed to roost on the branches, if they are strong enough. If not, perches should be placed under the trees. They should be removable, and should be of fir poles, broad enough for the birds to grip firmly and raised threc feet or so above the ground.

Sheds for the Birds. When turkeys must for one rcason or another, be accommodated under cover, a special form of shed is neces sary, because they need an ahundance of fresh air. The floor must be dry, and the roof should, if possible, be thatched and lofty. The walls should preferably be made of wattled furze about two feet thick, as this ensures, not only perfect ventilation, but fresh air without draught.

Turkeys usually remain on their perches until let out in the morning, when it is their habit to fly straight out and alight on the ground some distance in front of the roost. Therefore, to prevent the birds fiom damaging themsclves, the greater part of the front of the house should be made to open with folding doors or gates consisting of strong frames hung on hinges and covercd with wire netting.

Breeding Considerations. As regards brecding, close breeding should be avoildcd. Mere size is not very important. An approximation to 25 lb . in the males and 15 lb . in the females are suitable weights for ordinary brceding purposes, other considerations including width of shoulder, contour of breast, and a medium length of leg. Stock birds should preferably be from two to three years old, and eight or ten hens should be mated with one cock bird. Yearling hens are not recommended for breeding, but may be entployed as mothers during the first season.
The correct feeding of these stock birds is important. Their diet varies according to weather and other conditions, but a suitable mash can be prepared by using equal parts of ground oats, or barley meal and middlings, to which 5 or 10 per cent of meat meal may be added, with grain at night. Many brceders, however, prefer a whole grain diet for both morning and evening feeding, using wheat, barley and oats, and adding cabbages and swedes where the pasture is poor.
Much depends upon the supply of natural food available. When this is plentiful a supply of grain as stated above is sufficient, but when natural food is scarce some soft food in which meat has been nixed should be given three or four days a week. From January onward breeding turkeys necd to be in a hard sondition, and they must, therefore, have plenty of excrcise. A generous supply of grit and oyster shell is also essential.
During March the hen birds require watching, or they will choose an out-of-the-way spot in which to nest. It is therefore advisable to make up nests in sheltered and secluded positions in which the birds may lay their eggs. April is the best month for hatching, and it is generally undesirable to continuc hatching beyond June. Turkey hens are usually good mothers, but their eggs may also be hatched under barndoor hens. Artificial methods of hatohing and raising are not recommended, though incubators are sometimes used. A turkey hen will cover 15 or 16 eggs, and a large barndoor hen 8 or 10 . The period of incubation is 28 days. The
nests should be upon earth bottoms, and the the ordinary fowl's.
Care of Young Birds. In rearing young birds the principle of the roost house should, as far as possible, be applicd to the coops. The doors should be wire-netted and covered, if possible, in severe weather with sacking. The birds should be cooped with their natural or foster mother in a dry, sheltered position with a sunny aspect; a rich, medium soil is the most suitable. The coops must be moved a shoit distance daily to a fresh paitch, and the hens allowed out with the young birds whenever possible. The coops should be placed on short, fresh grass where the soil is quite sweet, and for the tirst 10 to 14 days they should be fitted with enclosed runs in front The coop and run should be moved daily to fresh ground.

Young turkeys should receive no food whatever for 36 hours after hatching. Afler that a suitable diet consists of steamed rice dried with fine sharps and mised with curds and finely chopped green food. With any soft food an admixture of finely chopped grass food, particularly dandelion leaves, clover and lettuce, is especially benelicial. It is important that the feeding board should be sprinkled with fine, sharp grit and powdered vegetable charcoal if curds are absent from the diet.

The fecding should be begun early and continued until late in the day. Very little food is required at one time, but it is necessary to give it at frequent intervals, commencing with six meals daily, and the soft lood allernated by a feed of coarse oatmeal and cracked wheat in equal parts. At about the third week the diet may be changed to include most of the foodstuffs given to ordinary chickens. Boiled wheat is also a good food during carly days. Later, new corn will be

Turkey. Handsome specimen of a full-grown turkey cock with wings and tail outspread
found helpful in the hirds' dict. Unless plenty of natural food is available, some meal must be included in the ration.

Fattening for the Table. The sclection and separation of the birds for stock purposes should be made during the autumn, preference being given to birds of good frame and stout legs, rather than to merely heavy specimens. The birds intended for fattening should be allowed full liberty until November. Until that time, in addition to the run of the ficld,
they should receive a liberal feed of grain twice a day The birds that respond mosi satisfactorily to the fattening process are those that have been kept in good condition from the carliest days.

About a month before they are to be killed the birds should be conlined at night in a large open-fronted shed situated in a quiet position. They must be liberated daily to prevent their fretting froin conlinement and to allow them exercise An abundance of soured skim milk or buttermilk is necessary in order to give colour and mellowness to the flesh, and, in addition, to stimulate, by the acid in the milk, the appetite which might otherwise fail.
A suitable food for these days is Sussex ground oats, wheat meal, or barley meal and sharps, and in many cases cooked potatocs or beetroots are mixed with the meal in the proportion of one part of the roots to two parts of meal. Soured skim milk or buttermilk is uscd for mixing the meals into a crumbly, moist condition. Once or twice weekly boiled meat offals should be given wilh the soft food The meat should be linely chopped, and the liquor used in place of milk for mixing the meals. The Sussex ground oats is made by grinding oats into a tinc meal. The special finely ground product is obtained by mixing a small proportion of barley with hird, llinty oats.

During the fattening period some give the birds rice boiled in milk, in order to whiten the flesh. lor the evening wheat, oats or barley is usually given in place of the mixture mentioned above, though some prefer to give soft food entirely. Plenty of grit, to which may be adder small pieces of vegetable charcoal, should be supplied in a box, or hopper, so that the birds may use a。 much as they want.

Turkeys should bo killed by dislocation of the neck after having been starved for 24 hours. They should be plucked at once. The birds should be plucked quite clean, except for the neck and the feathers on the back, covering the hips, which are ususally left on in order to prevent the skin from rubbing.

How to Cook. Turkeys are in perfection at the age of about 6 months. For braising or stewing, which demands long, slow cooking, an older bird may be used, but for roasting turkeys should be young and tender. Young turkeys arc known by their smooth black legs, bright eyes, red heads and supple feet. Immediately after they are killed they should be hung up to bleed and kept for 3 or 4 days before being cooked. Turkey may be boiled, roasted, braised, made into soup, or served cold. plainly or as a poultry salad.
To roast a turkey, singe and draw the bird, wash it as quickly as possible in cold water, and stuff it with chestnut stuffing or a good veal forcemeat. Sew it up, truss it as for a roast fowl, wrap it in greased piaper, and cook it in a good oven for about 2 hours. This is the time required for an averige-sized bird. Kcep it well basted and take the paper from the breast a little while before lifting the bird out of the oven. When it is ready, put it on a hot dish, remove the trussing threads and strings, and strain some good brown gravy round it. Fried rolls of bacon make a suitable garnish, and some extra gravy should be served in a sauceboat. Cranberry sauce (see page 312) is often liked with turkey. If preferred, fried sausage may be used instead of bacon, and sausage meat is often einployed for stulfing.

Boiled Turkey. Choose a medium-sized bird for boiling and, after plucking it, draw it by cutting off the bead, slipping down the skin round the neck, cutting off the neck and removing the crop. Turn the bird round and from the other end take out the inside, being careful not to break the gall bag. Cut
off the fcet and part of the legs to the first joint, draw the sinews, wipe the inside of the turkey, and truss it into shape.
To do this loosen the skin round the legs, draw the legs under it, press them well in so as to push up the breast, and skewer them into position or sew them with a trussing needle. Fold the loose skin from the neck over the back, and turn the wings and skewer them so that they keep this skin in position. Put some thin slices of lemon over the breast, then cover, the latter with a greased paper. The bird has next to be tied in a piece of ntaslin.

Put the turkey in a large pan of boiling water or stock, add a few mixed herbs tied in muslin, an onion stuck with a few cloves, and a carrot and turnip. Take out the herbs after $\frac{1}{2}$ hour's cooking, or they will discolour the stock. Simmer the turkey gently for about $2 \frac{1}{5}$ hours, keeping the stock well skimmed, then add 2 lb . of sausages and continuc cooking for another 40 min . Serve the turkey on a large dish, place the sausages round, and pour the sauce over all. Some of the liquor in which the turkey was cooked may be served separately.
Casserole of Turkey. Braising is a good way of cooking an old turkey. Pluck, singe, draw and cut the bird into neat joints, cover these with thin slices of fat bacon (remove the rind), place some more bacon at the bottom of a large casserole and lay the pieces of turkey on it. Add also the washed heart and liver. Peel and cut into dice 2 carrots, 2 turnips, and an onion, add them to the casserole with the green tops of 2 sticks of celery and 4 cloves, 12 peppercorns, and some parsley stalks, thyme and bayleaf tied together.
Pour in enough cereat or vegetable stock to cover half of the turkey, bring all to the boil, and then simmer gently for 4 or 5 hours. Serve in the casserole with the vegetables, but first skim the gravy, and if necessary add a few drops of browning. Season it to taste, and pour it over the turkey.

Devilled Turkey Legs. The legs of a cooked turkey make a dish in themselves if devilled according to the following directions: With a sharp knife score the legs round and lengthways in deep, regular gashes, brush them over first with melted butter and then with a mixture consisting of 1 teaspoonful each French and English mustard, 2 teaspoonfuls chopped chutney, and a sprinkling of salt, pepper, and cayennc. Over this sprinkle a few browned crumbs, then grill the legs on a greased gridiron before a clear fire.

When browned all over, serve them on a hot dish, with a few small lumps of butter placed here and there. Garnish with watercress.
Turkey Blanquette. For this method of using up the remains of a cold turkey, first put the bones into a stew pan, cover them with cold water, and cook them slowly for an hour. Then strain the liquor, and with it make some white sauce, seasoning it to tastc. To the sauce add some white pieces of turkey cut into neat squares: simmer all gently for about 20 min., and then draw the saucepan to the side of the fire.
Beat up the yolk of an egg with the juice of a lemon and a little of the hot sauce, and add it to the stew, stirring all the time. Return the pan to the fire, and continue stirring until its contents thicken, but take care that they do not boil or the egg will curdle. Just before serving, stir in a little finely chopped parsley. Triangles of fricd bread, placed round the dish on which the stew is served, are a good garnish.

TURKEY CARPET. The style of knotted floor coverings that is universally recognized as Turkey carpets or rugs comprises woollen fabrics with deep red grounds, bearing conventional medallion designs with broad horders, usually carried out in strong blues and yellows. A regular industry, with headquarters at

Istanhul and Smyrna, is engaged in meeting the demand for these productions from all parts of the wor!d, and the designs and sizes have been more or !ess standardized.

The term fancy Turkey is used for similar commercial makes, especially in carpet sizes, in which the colourings and designs are more varied. The grounds of these are available in greens, rose, orange, light blue, ivory, manves and pinks. There is a large output of Turkey patterns in British and continental makes, cspecially for stairs and corridors. By being able to tackle warps of considerable length, power-looms readily turn out these goods in the piece, although such carpets lack the hand-knotting of the native weavers.

There is a large production of carpets and rugs in Turkish lands, cspecially in Anatolia and Kurdistan. They differ from the more characteristic of the Persian rugs by being invariably made with the so-called Ghiordes or Turkish knot, one effect of which is to turn the nap toward the right or left top corner instead of atraight up the rug. They also usually have wool warps and wefts, often dyed to the prevailing colour of the design, with solvedged sides and knotted warp-ends.

Styles and Qualities. Various styles and qualities are distinguished by such names na Yapraks and Spartas. Some of them are very iooscly woven ; a Karaman, for example, may have not more than 10 knots to the square inch. There is also a modern output of fabrics made in the homes of the native population, in which the traditional features have a better chance of being perpetuated.

The Ghiordes ruge, formerly among the choicest of the Anatolians, and now often the poorest, frequently have a scparate web sewn on the upper end, instead of being finished with plain warp threads. Kulah rugs, mostly of the prayer type, and often passed off as Ghiordes, are readily recognized by their many narrow horder stripes, which may run to 14 in number. They usually have the field filled in with smallish objects instead of being left plain, and show one instead of two cross-panels outside the prayer niche. They are short-piled and almost lustreless, and generally contain in the border the distinctive Kulah design, which suggests derivation from the dragon associated with Central Asia.

A large class of small fabrics, generically known as Anatolian mats, cither display the varied characteristics of this region or reproduce more or less closely the more distinctive geometrical features of the Caucasian types. See Carpet; Persian Carpet ; Rug.

TURKEY RHUBARB. This drug-providing member of the rhubarb family is Rheum palmatum. It is an ornamental-leaved plant Hourishing in decp, rich soil in sunny positions near the water-side. Propagation is by division of the roots during the winter months. The drug is used as a stomachic and purgative. See Rhubarb.
TURKISH BATH. A Turkish bath is carried out in a number of rooms of different temperature, ranging from about $90^{\circ} \mathrm{F}$. in the coolest to $220^{\circ}$ or even higher in the hottest room. The greatest precautions should be taken to avoid exposure on the way home from the bath, which may lead to the contraction of a chill or severc cold. As a Turkish bath may be depressing, it is as well to have medical opinion as to one's fitness for taking it.

The hot-air bath is an improvised Turkish bath, and usually takes the form either of a portable cabinct or an arrangement for an invalid for which the only apparatus required is a large spirit or candle lamp with a metal funnel which can carry the hot air into a framework cage.
The interior of a hot-air bath cabinet is lined with asbestos. The heat is supplicd by a lamp as above or by electric lamps (the radiant heat bath). The patient sits on a chair in the bath.
and care should be taken that unprotected skin does not come into contact with parts which may be unduly hot. Thia bath may be used by healthy persons who wish to have the luxury of a Turkish bath at home, and it is desirable to follow it with cold sponging or a cold plunge. It is used with benefit, however, by persons affected with chronic rhcumatism and rheumatoid arthritis, and in their casc the application of cold must be graded to their capacity to bear it.
The hot-air bath in bed may be used in acute nephritis in place of the warm bath or the vapour bath. See Skin; Vapour Bath.
Making a Bath Cabinet. A folding vapourbath cabinet that can be made casily by the home craftsman is illustrated in Fig. 1, and consists of four sides hinged together and provided with a flexible top. Inside measurements can be varied to suit requirements: in the example given they provide a squarc floor space of 2 ft .9 in . and a height of 3 ft .6 in . The floor should be covered with a plece of stout cork linoleum measuring at least 3 ft .6 in. squarc.
The sides, as shown in Fig. 2, are made of either $\frac{8}{18}$ in. or $\frac{1}{4} \mathrm{in}$. plywood secured to a framework of $1 \frac{8}{4} \mathrm{in}$. by $\frac{8}{4} \mathrm{in}$. wood. Many of the manufactured baths are made with a framework of wood covered on one or both sides with a closely woven canvas or American cloth, but the plywood covered frame is more satisfactory, as there is little risk of its being damaged, which is the main disadvantage of the cloth-covered frame. The construction of the framework is quite simple: two of the sides aro 2 ft .10 in . wirle, the others are 2 ft .11 in . and 2 ft .9 in . wide, and all four are 3 ft .0 in . high.

The method of attaching the frames, as shown in the plan at Fig. 3, allows of the side A being turned back on the side B , the side at $C$ is folded back on $B$, and the remaining side, D , which acts on the door, folds back on the side $C$. The wood for the framing should be machine-planed to the required width and thickness: if not, it must be hand-planed from 2 in. by 1 in . deal batten selected in straight lengtlis and free from knots and blemishes. For the uprights eight lengths of $3 \mathrm{ft} .6 \frac{1}{2} \mathrm{in}$. should be sawn off and four lengths of 2 ft . $10 \frac{1}{2} \mathrm{in}$., two of 2 ft . $11 \frac{1}{2} \mathrm{in}$., and two of $2 \mathrm{ft} .9 \frac{1}{2} \mathrm{in}$. should be cut off for the rails.

Place the uprights in pairs and set off 4 in . from one end, then $1 \frac{3}{3}$ in., and from this mark set out 3 ft . $2 \frac{1}{2} \mathrm{in}$., taking care that all the pairs are accurately measured to the same distances. The four 2 ft .10 in . lengths are marked out together, the first mark being $\frac{1}{2}$., the next $1 \frac{3}{4} \mathrm{in}$., and the third $2 \mathrm{ft} .6 \frac{1}{2} \mathrm{in}$. The 2 ft .11 in . pieces are placed together and the first two marks are the same, but the third is $2 \mathrm{ft} .7 \frac{1}{2} \mathrm{in}$., while the remaining pair are marked off with the same two distances at the end with a 2 ft . $5 \frac{1}{2} \mathrm{in}$. distance for the third mark.

The frames are fixed together with halved joints, as shown in Fig. 4. A marking gauge is set to $\frac{I^{3} \mathrm{in} \text {., and lines are gauged from the }}{}$ face side of each piece across the ends and down each side to the inner mark. A pancil mark is made at the ends of the uprights on the opposite side to the face, and on the rails on the face side to indicats the waste. The ends are sawn down on the waste side of the gauge lines in each case, and then the waste cut off at the shoulders, care being taken not to saw beyond the lines. The plywond is cut to the required sizes, two are 3 ft . 6 in . by 2 ft .10 in ., one is 3 ft .6 in . by 2 ft .11 in ., and the other 3 ft .6 in . by 2 ft .9 in . To allow for cleaning up the cdges, these sizes may be exceeded by $\frac{1}{1}$ in.

The frames should be glued up and a screw driven in each joint, but they must bc tested for squareness. The best method of doing this is to take a thin lath, place it diagonally
between opposite corners, and mark. If on placing the lath on the opposite diagona! the marks coincide, the frame will be square ; if not, the necessary adjustment must be made. The frames are now glued to the plywood and further secured by screws driven in at intervals with the screw holes countersunk. When the glue has set hard, the projecting ends of the framing are sawn off and the edges of the plywood planed down to the outer surface of the frame. The wood is cleaned up with glass paper and coated with size before varnishing.
The positions of the hinges are shown in Fig. 3. At F the hinges are screwed to the end of $A$ and at the back of $B$; at $F$ they are screwod to the inside of $B$ and $C$, and the hinges at $G$ are fitted as at $E$ to the outside. in this case to $\mathbf{C}$ and D . Ordinary butt hinges or back flaps can be used, but the appearance of the work will be improved if the hinges aro let in flush with the surface. In order to make the joints conparatively vapour-tight, rubber draught strip should be tacked to the uprights as in the sectional detail at Fig. 4. The same material is tacked along the edge of the door piece D on the outer upright of the side $A$, so that the door can butt against it. It will also be an advantage to edge the bottom rails with

Turkish Bath. Fig. 1. Folding vapour bath cabinet. Fig. 2. Measurements of sides. Fig. 3. Plan. showing method of attaching frames. Fig. 4. Balveil joint and position of rabber draught strip. Fig. 5. Portion of flexible top
the rubber st rip. To keep the door fast when closed, two hoolis and eyes should be fastened on the inside.

The top can be made of any closely woven material, but rubber sheeting is the inost suitable. It is marle in two portions, as in Fig. 5, which shows the dimensions for narking out, each piece being 3 ft .3 in . by 1 ft .10 in ., with an opening of 11 in . dianeter in the centre of one side. Commence by marking off a line 1 in. away on one side and both ends, and on the same side set off lines 2 in. inside and make cuts 3 in. long as at $H$. On the other side set off two lit in. lines and cut the opening with the centre on the inner line; the diameter can be lessened if required. The material to the first line is turned under and sewn ; at the same time the material is folded at right angles at the inner 2 in. line and the corners sewn up with the hem. The edges surrounding the opening can be hemned. but the neatest method is to bind it with a roll
cut through one of the sides or a hole A small gas stove can he fitted or one of the small oil stoves of the Beatsice type. A bentwood chair with a perforated wood seat forms the most convenient seating accommodation. For steam or vapour, the water or vaporizing solution should be placed in a shallow pan on top of the stove.

When using the batl, the sides are arranged on a mat or square of linoleum and the top fastened to the sicles and back. The lamp is lighted and regulated and placed in position. The user enters the cabinet, the door is closed, and the top, fastened to the door and buttoned below the head, which is, of course, outside the covering. The outside heater has advantages, as it can be regulated hy an attendant. but it is somewhat difficult to regulate an inside heating arrangement. The correct temperature can lie found after one or two trials. After use, the sides are wiped with a dry cloth
and the cover dried before being packed away.

TURKISH COFFEE. More carc is required for the preparation of Turkish coffec than of ordinary coffce. The metal pots in which it is made are sold specially for the purpose, and have long handles and spouts. They are heated on the small stands with which they are sold. The coffec nust be very fresh and very finely ground.

Enough Turkish coffee for two people can be prepared by putting 2 or 3 lumps of sugar and $\frac{1}{2}$ pint water into the pot, boiling them and then drawing the pot away from the flame while 2 large tablespoonfuls coffee are added. Reboil the whole, take the pot from the flame again for a second or two, and repeat the reboiling 3 times. Serve the coffee without milk in small cups. See Coffce.
TURKISH DELIGHT. This is a favouritc Eastern sweetmeat which is imported into Great Britain. The following is a good recipe. Take 2 lb . loaf sugar and make it into a syrup with 2 pt. water. This syrup sliould be cleared with the whites of 2 eggs. Add 2 tablespoonfuls lemon-juice and turn all into a sugar hoiler; meanwhile dissolve in $\frac{1}{2}$ pint water 4 oz . rice starch, and when the syrup in the pan hoils stir in the dissolved starch and cook all gently, stirring the whole time until the mixture is firm and has been reduced to $\frac{1}{3}$ of its original hulk. Pour half the mixture into another pan, colour it pink, and favour with rose cesence. The remaining half should be sufficiently Havoured with the lemon, but if not add a little essence. Havc ready a few blanched almonds and pistachio nuts cut in pieces. Add some of each to both portions of delight.

Set the inixture between candy bars on a slab dredged with confectioners' starch or icing sugar and cornfour. A tin similarly prepared

Turkish Delight. A favourite soft sweetmeat
may be used instead of the bars. When set, divide into blocks, roll well in starch and sugar, and store in a wooden box with plenty of stareh and sugar. Line the box with wax paper. Another method is as follows: Soak 1 oz . gelatine in $\frac{1}{2}$ gill water in a saucepan and stir over heat till it boils; let it simmer 3 or 4 inin. Place in a large saucepan l lb. granulater sugar with another $\frac{1}{2}$ gill water, melt slowly, and bring to boiling point, then remove from the fire and cool slightly. Add the dissolved gelatine and boil for 20 min ., stirring all the time. Add 1 tablespoonful rum, the juice of an orange and of a lemon, and a strip of thinly cut lemon rind. Stand this for $: 0$ min. in a warm place, then colour half pink and flavour with rose essence. Add a few nute to each portion, and cut separately. See Sweets.
TURK'S CAP LILY. Two lilies are known by this popular name. Of these Lilium chal. cedonicum bears blossoms of scarlet with petals rolled back, while martagon has tiers of drooping, recurved purplish Howers. A beautiful variety of the latter bears waxy white Howers. See Border; Lily.

TURMERIC. The roots of the turmeric plant yield a condiment which is uscd in the preparation of mustard, curry powder, and pickles, and is also of commercial valuc for dyeing purposes. It must be grown under glass in Great Britain.

TURN RUCKLE. This name is given to $n$ typc of straining device, and also to a fastener for a cupboard door. Dealing first with the former appliance, the turn buckle, or bottle screw, comprises a body in which are serewed
one or more portions adapted to receive wood shaped at both ends and bored with a the ends of wires, cords, or the like. The hole for a screw. common type has two screwed ends, and will thus exert a tersion upon two cords simultaneously, this usually being accomplished by providing the body with some form of rotation, threading one end with a right-handed threarl and the other with a left-handed thread, the cye bolts or screwed portions being similarly threaded. When the body portion is turned with a spanner or a tommy bar the screwed portions arc drawn together, so tensioning the guy rope or straining wire to which the turn buckle is attached.

Numerous varieties of this style of turn buckle are available, and should be chosen according to their utility, length of travel, and so forth. When used out of doors, for example, as a means of tightening the stay wires supporting an acrial mast, they should preferably be of galvanized iron or some other

non-corrosive material. They should also have a fairly long travel, something in the nature of 6 in. being practical for the average wireless mast.

## Cupboard Turn

 Buckle. 'The second type of turn buckle, for sccuring cup. board doors and other hinged structures, comprises a neerled, and a which a square, sciewed shank turns, the outer the proportions are reversed. Information on end being provided with a handle and the the choice of a lathe for either of the specitic inner end having a small lever adjustably uses is given in the article on Lathe. The attached to the spindle. The lever is fixed amateur may well consider the purchase of either with a small setscrew or by a screw a Verschoyle mandrel (see page 697, Fig. 4), thread and lock nut. In use the spindle passes through a clearance hole drilled through the framework of the door, the plate being screwed to the outside. The position of the lever is adjusted on the spindle so that when the door is closed and the handle turned the lever stands at right angles or parallel with the floor, thus preventing the door from opening. Sometimes the fastener is provided with a more ornate plate and a drop handle, when it is usual to dispose the handle so that when it is in a vertical position the lever is horizontal. This prevents the weight of the lever rotating the handle and so allowing the door to open.There is another kind of turn buckle which is used chiefly for securing shutters. It is in the form of a pivoted cateh which operates by gravity, the weight of the handle being so disposed that it kecps the catch normally in a locked position.
Cupboard turns are liable to wear the cdge of the door, especially if carclessly used. To avoid this and to repair worn doors, a neat angle plate should ne litted on the opposite door. It can be made in thin brass and let into the wood; the screws used should be placed in countersunk holes. In fitting all turn buttons care must be taken to clear the edge of the door frame and allow sufficient projection to hold the door. See Aerial; Cupboard ; Door.

TURN BUTTON. Used for fastening doors and flaps, the turn button is made in wood and metal. The simplest form is shown in Fig. 1, and consists of a small piece of hard.

Turn buttons in japanned iron and brass are of the shape shown in lig. 2; those made in iron are ohtainable in sizes from $1 \frac{1}{2} \mathrm{in}$. increasing by $\frac{1}{f} \mathrm{in}$. to $2 \frac{1}{2} \mathrm{in}$. The same pattern in brass increases in like proportion from $\frac{3}{4} \mathrm{in}$. to $2 \frac{1}{2} \mathrm{in}$. Half buttons, as in Fig. 3, in japanned iron can be obtained from $1 \frac{3}{4} \mathrm{in}$. to 2 in., and in brass from $\frac{3}{4} \mathrm{in}$. to 1 in . A neater form of turn button is shown in Fig. 4, the button being riveted to a brass plate, and the corresponding metal plate being attached to the face of the door stile. This is used on thin wood or where extra neatness is clesired, and it should be attached by means of Hathcaded brass screws. One great advantage of this type is that the button cannot wear away the cdge of the door, as often happens with the common pattern. See Cupboard; Door.
TURNING. The mechanical processes which are grouped under the gencral heading of turning divide into two independent groups, those associated with the turning of wood, which are dealt with in this Encyclopedia under the heading of wood turning, and the whole series which apply substantially to the turning of any kind of metal and inost of the manufactured compositions, such as ebonite, celluloid, and the like. These are treated under the titleof metalturning (q.v.). The mechanical requirements of the wood and metal turner respectively are somewhat different. For wood turning a lathe with a large Aywhcel is
Turn Buckle. Fig. 1. Turn buckle and hook for use as a strain-
ing device. Fig. 2. Type of cuphoard turn buckle, showing a cupboard door

TURNIP. A prolonged supply of this favourite root vegetable can be assured by sowing the seeds out of doors in March and early April for summer produce and in late Juneand carly July for an autumn crop. Ordinary well cultivated soil frec from fresh manure is suitable. For spring sowing the drills should be 12 in . apart; the seeds need only a slight covering of soil. To allow them full room for development the seedlings ought to be thinned out to 4 or 5 in. apart. Suitable varieties for spring sowing are Early Snowball, Early Milan, and Six Weeks.

The seedlings of autumnturnips should be thinned out to 6 or 8 in. apart ; some of the best varicties arn

Snowball,
Greentop Stone and ChirkCastle. Those who like yellowfleshed tur nips should choose Golden Ball or Orange Jelly, and sow the seeds in July. An carly varicty of turnip miay be sown on a bed of fine soil on a hothed of nianure made up in a franie in January. If turnips are

Fig. 1

Turn Button. Fig. 1. Simple form in hardwood. Fig. 2. Turn button in japanned iron or brass. Fig. 3 . button riveted to a brass plate
doors in August and September the leafy tops will provide a useful winter vegetable.
The Turnip Flea. The turnip flea or fly is the most troublesome pest of this vegetable. It attacks the seedlings and riddles the leaves. Frequent dustings of soot are recommended, together with an occasional application of nitrate of soda, l oz. per square yard of row, to encourage the seedlings to grow quickly and strongly.
Cooking Turnips. The turnip is served as a vegetable with boiled mutton, and it can be made into various dishes of dressed vegetables. It is also used for flavouring soups. Old turnips should never be served as a vegetable, as no amount of boiling will render them tender, but they can be used for flavouring. The turnip is not easily digested by delicate persons or invalids.
To prepare turnips for boiling, pare them thickly and always under the brown line which is apparent when the pecl is cut into. As they are pared divide them into halves or quarters nnd throw them into cold water. Have ready a good-sized pan of boiling water, as they need plenty of room when being boiled. Young turnips take about $\frac{3}{4}$ hour to cook and those which are rather more matured $1 \ddagger$ hours. When the turnips are cooked, drain them thoroughly and press then in the colander with a vegetable presser in order to extract

all moisture, then rub them through a wire sieve or pass them through a mincer. Rinse out the pan in which they were boiled and melt in it $\frac{1}{2}$ oz. butter for each Ib . of turnips (weight before cooking) and $\frac{1}{2}$ gill milk, scason with salt and pepper, then return the turnips to the pan and heat all together over the fire. If preferred, the butter may be omitted, but niargarine should not be substituted, ns it is too oily.
To stew turnips, pare and wash them and cut them first into slices and then into dice. Allow for each lb . of turnips 2 oz . butter and melt it in a stewpan. Add the pieces of turnip, put on the lid, and stew very gently from $\frac{3}{4}$ to $l$ hour. Stir freguently, and when half cooked add seasoning. This method of cooking turnips is suitable for scrving them in the centre of a dish of cutlets or for garnishing. They may also be served with a roast leg of lamb. A little chopped parsley sprinkled over then adds to their appearance. See Kohl Rabi.
TURNOVER. The turnover is made with short or llaky pastry, rolled about $\frac{1}{2}$ in. thick. The shape may vary, but the filling, which may be savoury or sweet, is always placed in the centre, one half of the sliape being folded over until the extreme edges meet. Cornish Pasty ; Jam Turnover ; Pastry.

TURN THE TRENCHER. This is always a popular game with small children, and is very pretty to watch. All that is needed is a bread trencher, or a amall, round tray. 'The children sit in a circle, and each chooses some article of a lady's toilet, c.g. brush, comb, hairpin, sponge, etc. The person leading the game then tells a story, describing how some young and beautiful lady is getting ready for a ball. As each article of the toilet is mentioned, the child who represents it has to spring into the centre where the trencher is lying and give it a brisk spin.
Another way of playing the game is for each child to choose a llower. One then picks up the trencher and spins it, at the same time calling out one of the Howers, and the child called has to catch the trencher before it stops spinning, or pay a forfeit. It will be seen that the game lends itself to much variety as far as the names are concerned: they might be animals or birds, or even parts of a motor car. In the latter case it could be modelled on liamily Coach. See Children's Party; Forfcits.
TURPENTINE. Oil of turpentine is a colourless thind with a peculiar balsamic odour and pungent, bitter taste. Externally it may be used as turpentine liniment or the acetic liniment of turpentine. Sprinkled on a lot fomentation it makes a turpentine stupe, which is often applied to the abdomen to relieve colic and gaseous distrnsion. It may prove of valua in neuralgia, lumbago, and other forms of muscular rheumatism, and in the later treatment of a sprain.
The uses of turpentine in the home are many and varied. Its odour helps to keep away black beetles, ants, flics, and mice, and shelves and cuphoards sprinkled with it are rarely troubled by insects. A little turpentinc sprinkled in boxes or wardrobe where woollen clothes are stored will also keep out moths.
Paint stains on clothes can be removed with turpentino and household ammonia. Dip the stain first in turpentine and then in ammonia, rubbing it after each immersion. If the stain is not an obstinate one, turpentine alone is often suflicient. Grease marks on coloured fabrics will also yield to vigorous rubbing with turpentine. Place the stained part over a cloth, and rub it with a clean rag dipped in turpentine, until the spot is dry.

Turpentine has antiseptic propertics, and its use in the home can therefore also be recommended on medical grounds. See Clothes; Grease; Paint; Patent Lcather.

Turnip. Fine round roots of the green top white turnip TURQUOISE. An opaque sky-bluc or sold in their natural cream to brown shade greenish -bluc stone, the turquoise owes its which witlsstands any amount of washing and popularity mainly to its colour. It is sometimes exposure. See Shantung; Silk. set in rings, but, being very easily scratched, it is better suited to pendants, brooches, and necklaces. While the turquoise cannot be classed with the more precious gems, large stones of good colour fetch a high price. They are subject to changes of colour.

TUSK TENON. The joint used in carpentry under the name of the tusk tenon is so called because the tenon itself is longer than usual and extends beyond the face of the material to which it is jointed. It is held by means of a wedge driven through a hole near the outer end of the tenon.

The disposition of the parts is shown in the accompanying illustration of a trimmer tenoned and wedged to a floor joist. This joint is largely used in building construction for all openings through floors and ceilings, the chief reason being that the wedge holds the tenoned member firm against the rafters or joists, and prevents the latter from springing or starting.

The length of the tenon which extends beyond the rafter should he at least equal to the thickness of the rafter through which it passes. It is shaped and fitted in the same way as a tenon joint, after which the exact position for the wedge is marked, the tenon withdrawn from the mortise, and a hole drilled through, using a brace and large diameter bit. The hole has to be enlarged with a paring chisel, and the outer facs should be slightly tapered. The Tusk Tenon. The completed joint The inner face, that is, the side nearest to the shoulder, is cut back so that the wedge will bear firmly against the outcr face of the rafter and the outer inclined face on the tenon. The wedge must not bear on the inner wall of the hole through the tenon. The wedge should be preferably of hardwood tapered to suit the hole, and should fit exactly. When the trimmers have been fixed in place, the wedges arc inserted, the rafters preferably being crainped together while the wedges are driven homc. See Floor; Tenon.

TUSSILAGO. This is the botanical name of coltsfoot (Tussilago farfara), a common British weed which bears yellow daisy-like flowers in early spring. For cultivation in gardens the best species is the winter heliotrope, Tussilago (petasites) fragrans, a hardy

TUTSAN. Sometimes known as swect amber, the tutsan is a shrubby species of Hypericuin, H. androsaemum, suitable for growing on banks or under the shade of trees. It bears yellow Howers similar to other members of the St. John's wort family. The tutsan is evergreen, and only requires trimning during April.

TUTTI-FRUTTI. Sometimes referred to as a mixed fruit ice, the sweet called tuttifrutti is prepared by cutting up sonce mixed fruit, dredging it with castor sugar, and soaking it with a little liqueur. When it has stood for a short time it is stirred into some half-frozen water ice, and then the frecziag is continucd. See Frcezer ; Ice.

TWEED: The Material. Hand-spun and woven tweeds are necessarily expensive 10 produce and command high prices. Harris tweeds made in the Hebrides carry with them a peculiar odour of peat-smoke, and of certain of the ingredients used by the dyer. Donegal tweeds, in which there arc usua!ly lumpy, brightcoloured irregularitics, are much liked for sports wear.

Scotch tweeds, machine made in scotland, are amongst the best wearing, and arc procurable in heather mixtures, checks and thecked designs, and in heavy, mediuin or gossamer weights. Hand-made tweeds do not usually wear as well as the best machine-made. The cheapest mill-made tweeds are often of very poor quality, containing much shoddy and cotton. See Harris Twiced; Loom; Weaving.

TWEEZERS. Miniature pincers known as tweczers are sold by chemists and beauty specialists for removing superlluous hair from the face, especially from the cyebrows. It is not claimed for tweczers that they destroy the roots of the hair, but their frequent use has a weakening effect. Tweczers are intended as a remedy only for slight growths of hair. See Electrolysis.

TWELFTH NIGHT CAKE. If a children's party is held on the l2th day after Christmas, Jan. 6th, a Twelfth Night cake is sometimes specially made for the occasion. The cake is after the style of a Christmas cake, and ornamented with icing and coloured candies or candied fruits. Sometimes 12 small candles
are distributed round the iced top, as is done with birthday calics, and there may be a large gilt star in the centrc.

TWILIGHT SLEEP. When childbirth is conducter under the influence of seopolamine and morphine the drowsiness induced by thesc drugs may be made sufficient to send the patient to sleep in the intervals of the labour pains. Such a condition is popularly referred to as twilight slecp.

Pain is not abolished by such treatment, and, indecd, it would be dangerous to attempt this. The inemory of pain may be aholished, however, so that although the patient, on the occurrence of labour pains, may have given obvious indications of suffering, yet at tho conclusion of labour she may know nothing of this.
The method is not required for short, labours, as in these a few whiffs of chloroform may sufficiently ease the paings, hut in prolonged labours twilight sleep may be a decided advantage. It should, of course, be supervised by a doctor. See Childbirth.

TWILL: The Material. For materials of all kinds the method of weaving known as twill is employed, the threads being so arranger as to throw up diagonal ribs upon the surface of the cloth. Cloths are mado to frel thicker by being twilled than if plainwoven. It is apparent that the twill lines commonly seen upon cloths vary in width, some being much coarser than others. Also they vary in the steepness of the diagonal, and the higher angles are most met in the fincr and more closely woven fabrics.

In addition to plain twills, there are the fancy sorts, twilled alternately in opposite direction to form herringbones or cherrons, and these cloths are generally satisfactory, is this method binds the threads firmly together. Twill cloths are not always alike front and back, and some of the most solid twills used for coats and costumes have a plain back.
In twilled shects made in the best manner, the strongest threads are brought up to the surface and takic most of the wear. (heap) sheets are often twilled and made partly from good cotton and partly from cotton wastc. They feel thick and soft, but the twilled ribs are lumpy and irregular, whereas in the hetter qualities the twill lines are sharp and smooth.
Most linings arc twills, and so aro all serges and many tweeds. Gabardine is a kind of twill, and so is Venctian. Some of the hardest wearing cloths for riding brecches are twilled. The best velveteens are woven with twilled backs to hold the pile more tirmly. Twilled mattings do well for kitchen and cottage floors.
TWINE. This is the name given to a strong thread madt up of two or threc strands, twisted, or twined, tightly together. Usually stronger and of better quality than string, its uses are practically identical. See String.
TWO STEP. This was a simple ballroom dance at one time danced as part of the for trot. The steps were similar to those in the galop, but danced more slowly, being written to six-eight time, although they could be danced to four-four time.
The man's steps were as follow's: Glide the left foot to the second position. bring the right up behind the left, glide the left again to the side. Repeat the movement, beginning with the right foot. The girl's step was the same, but slic began with the right foot. See Jancing; Galop: Roger de Coverley.

TWO STROKE ENGINE. This is a type of internal combustion engine in which the cycle of operations comprises one power stroke at every downward stroke of the
piston. It is contrasted with the four stroke engine, in which the power stroke occurs at alternate downward strokes of the piston. See Four-Stroke: Internal Combustion Engine: Motor Cyelc.

TYDAEA. This is a group of hothouse decorative plants with flowers of various showy colours. They flourish in the usual potting inixture of loam, !caf-mould, and sand, in shady positions.

Propagation is by secds sown in a mixture of sand and leaf-mould in the springtime, by cuttings of the young shoots at the same period, or by separating the rhizomatous roots. Rhizomes should be planted in 5 in . pots, several in a pot, in spring to llower in summer.

TYING: Of Plants. The staking of trees and plants is of great importance, and, as a rulc, duc attention is paid to the selection and placing of supports, but the work is often rendered ineffectivc or even entirely useless by the neglect of proper tying. The material used for tying trces must be strong enough to atand sudden strains ; it must also be sufficiently sound to hold securely for a considerabic time without rotling.

A knot is required that.will hold firm under practically any strain, and can be united casily. The knot that best answers these requirements is the ordinary reef or sailor's knot. Green raflia is an excellent material for tying plants to their supports.

## Typewriters: Their Use and Care

## How to Ensure the Working Efficiency of These Machines

Followed by an entry on typewriting, this article deals with the management and care of the
typewriter. Articles on subiects for which the typewriter is useful include Letter; Postage typewriter. Articles on subiects for which the typewriter is useful include Letter; Postage

Typewriters may dall into one of two classes. The type may be arranged round the circumference of a wheel or a segment, as for example in the Hanimond, the action of the keys rotating this whee! until the particular letter struck on the keyboard is brought opposite the printing point; or, alternatively, the type is carried at the end of levers or type-hars which strike the paper when the keys are depressed. Typewriters of the sccond class are much more numerous than those of the first, cxamples being the Empire Remington, Oliver, etc.

Various devices are employed for inking the type. This myy be accomplished by means of an ink-pad before thie depression of the keys causes the levers to move and the type to strike the paper but nore commonly an inked ribbon is inserted loetween the paper and the type. This ribbon is wound from one spool to a sccond by the action of the machinc, and so it is not worn threadbare at any particular point. A further variation is a ribbon in two colours, typing in red or black being performed by bringing the necessary part of the ribbon opposite the type-face.
A third classification may be found in the arrangement of the keyboard. Occasionally there is ono key for each character. Thus the capital A B C and the small a b c would each have a separate key, the capital and the small letters being arranged in two banks

Often each key strikes a capital letter, a small letter, a figure, or a punctuat:on mark, the particular impres. sion depending on the use of a sub sidiary key brought into use simu!tane ously with the letter key These sub sidiary or shift keys move the carriage forward, or backward, or into midposition as required for the character to be used. Obviously this type of machine is preferable, since the construction is simpler and therefore less costly. AII machines are fitted with the universal keyboard, so that it is an easy matter for anyone who has

By courtes/l of Remington T!/pewriler Co., Lld.
learnt on one machine to work equally well on one produced by a different firm.
The Essential Operations. Although there are many kinds of typewriters, with numberless differences in detail, tho mechanical parts of each bear a close relation to one another. The essential operations may be reducel to two. When tho key is struck a letter must be printed, and the paper nust be carried a short distance to the left before a second !etter is impressed, so that the letters are printed scparately, and not one on top of the other. The mechanism of the first of these operations has been described, and for the second it is better to wateh a machine actually at work.
It will suffice here to say that the action depends upon the mainspring and the dogs and rack. The mainspring is trying all the time to pull the carriage right across to the left, and would do so but for the dogs and the rack. Each time a letter is struck the mainspring is allowed to pull the carriage along to the width of onc letter, after which the next tooth in the rack stops further progress until another letter is struck.
Other Points to Note. Apart from these two main actions, a typewriter may be fitted with many subsidiary appliances. A bell may give warning of the end of a line, a lock may prevent the machine working after the end of the line is ruached, there may be attachments for corrections and tabulation, for facilitating the insertion of fresh paper, and the like. But it must be confessed that many of these innovations, althougb ureful, are intro. duced by the manufacturers to add points to their advertisements, and the first thing an expert typist often does is to disconnect and remove most of these additional luxuries.

Most typewriters have been modified to perform visible writing, which is, indced, put forward by the manufacturers as a recommendation of great im. portance. Possibly a
beginner may like to see that the letter printed corresponds to the key struck, or intended to be struck, but a practised typist no more needs to look at the keyboord than a pianist needs to look at the keyboard of his piano. A mistake is usually felt automatically, without any refer. ence to the typing.

Accuracy of alinement is essential. To ensure this has called for grent ingenuity on the part of the designers, confronted with the problem of making a system of levers at once strong, rigid, nud light, and of sup. porting them on bearings which are steady and adjustable for wear in conditions where space is much reatricted.

A tabulator is a very useful device whon complicated tabular work has to be carried out. The carriage can be moved instantaneously from any point in one column to nny point in another column, while the columus themselves can be arranged along the width of the paper.

Portable Machines. Portable typewriters are made of the toughest materinls and designed to eesist rust, survive neglect, and withstand all the bumping incidental to travel. The three principal makies of these portable typewriters are the Remington, which is here illustrated, the Corona, and the Underwood. Each of these, without the casc, weighs $6 \frac{1}{\mathrm{l}} \mathrm{lh}$. ; with case the Corona weighs 9 lb . and the Underwood 8 Ib. One general rule should be followed by the operator-his or her attention should be confined to oiling the machine and keeping it frec from dust. The less tinkering there is with a screwdriver or spanner the longer the inachine will givo cfficient service. Permanent loss of alinement and similar troubles are iew if a typewriter is properly oiled and dusted.

Cleaning the Machine. Cleaning is a very simple operation. Once a day the machine should be dusted over with a soft rag, the bright parts being rubbed over occasionally with a piece of chamois leather. Any accummlation of dust from orasures or the surface of the paper used in the interior of the machine can be removed by using a long-handled brush sold for this purpose. Oiling is almost as simple an operation. Use only a fine quality of typewriter oil, non-gummy, and oil judiciously. Too much oil is as bad as too little. Ordinary oil clogs the mechaniam.

A small camel-hair brush is a convenient method of oiling every joint and moving part of contact where friction can be caused. The mechanism should be thoroughly oiled and cleaned regularly -say, once a weck.

The post of the spring drum and the dogs of tho: cscapement should bs: oiled twice a week. any superfluous oil being afterwards wiped off. and occasionally, about every six months, the type-bar bearings alould receive a drop of oil. A daming needle dipped into the oil bottle will collect suftivient oil in the eye for each individual bearing.

Other parts should only be oiled when a squeak is heard, and in these cases the squeaks inust be traced to their source, and there treated. The machine rhould not he given a wholesale oiling to remove a single squeak. Sliding contacts should always be wiped clean before oiling to remove dirt and gum, and after oiling all surplus outside the spot of friction should be wiped off. If this is not done the oil, instead of acting as a lubricant, will attract a large amount of dust and check the sinootl working of the mechanism. If infrequent use or neglect has caused any

Typewriter. Remington portable model, showing names of principal parts Ry courles!y of the Remington Typewriler Co., I.d
parts to become stuck with gum, citleer kero sine or benzine may be used for clcaning, afterwarda oiling in the usual manner.
The type, which must never be allowed to become filled with dirt from the ribbon, is best cleaned by a type brush and a drop of benzine. The letters should be taken in their regular order, depressing a key with a finger of the right hand, so as to push the type-bar forward, when it is held by the thumb and forefinger of the left hand, and cleaned with the bristles of the brush with a downward and not a circular movement. The type-bar is held in this manner to avoid straining the bearings, and should be released gently. If the round characters have become very much clogged with ink or dirt, the point of a pin may be used with advantage, although the nccessity for this should be avoided by frequent cleaning when possible.
Rust on the bright parts is usually caused by settling dust, which holds moist ure from the air. If the machine is clusted regularly,
rust will not usually make its appearance. A rust will not usually make its appearance. A
piece of chamois leather should be kept for rubbing the plated parts, and, of course, when not in use the machine slould always be protected by its cover.
Just ns a piano nceds attention every few months. so a typewriter should be given a thorough overhauling by the makers or other responsible lirm every few years. As originally sent out from the factory, all machines are accurately alined, and unless the instrument is abused, it should not be necessary to return it for overhauling for at least five years. Mechanical intricacies, such as the readjustment of alinement, should never be attempted by the typisi.
Ribbons and Stationery. Good typewriting can hardly be expected unless the ribbons and stationery employed are of the best quality. A good ribbon should neither be thin and short-lived on the one hand, nor thick and muddy on the other. Even when new a good ribbon, nssuming correct touch, will give delicate work, and it should last from 300 to 600 hours say, on an average, 500 hours. If a ribbon supplied by a good firm gives less than $30(0-40)(1)$ hours' work, it may be taken for granted that the operator's touch is too heavy, and an attempt should be made to lighten it. Even when a rihbon grows faint, its useful period is by no means over, since there will be still a large amount of ink on the sicle of the ribbon away from the paper. If the ribhon is turned, its life can, therefore, be prolonged by $30-40$ per cen 1 .

Ribbons are in different sizes and of different colours, and it is important to see that the machine is fitted with a ribbon of the right
size. A ribbon which is too wide has to be cut down, a dirty and cumbersome proccss, while on a ribbon which is too narrow one sct of type may not strike at all. Both the ordinary noncopying ribbon and the copying ribbon for use with the letterbook can be obtained in all ordinary colours. In addition to these there is the hectograph ribbon for use with the jelly copying process: the lithograph ribbon, for making lithographic transfers for use by the printer in striking off a number of copies; and the indelible ribbon, the results of which cannot be erased from the letter-book once the writing has been passed through

A cheap typewriting paper casily rubs into holes, and shows patches wherever any erasures have been made. The best of workers make occasional mistakes, and unlcss good paper has been used the corrections will show. Cheap paper may, of course, be used during practice, but never on actual work.

Envelopes of ordinary shape and make. unless they are of thin paper, usually give a double impression where the paper is double, that part of the envelope upon which the gummed flap is secured. To avoid this, special typewriter envelopes, in which the whole paper surface is even and level, should be employed.

TYPEWRITING. The most obvious necessity for a person wishing to become an expert typist is practice, but no amount of practice will teach the finer shades of the work. nor will practice alone produce the high speed which may be attained by means of the best methods. The touch inethod increases speed enorinously, because the typist does not look at the keys at all, but can keep the eyes on the copy the whole time.
In typing it is important to use all the fingers, much as in playing the piano. The position at the machine should also be much the same as that of a pianist, with the elbows on a line with the wrists. The right thumb should be used for the space bar. The touch should be even and steady, and not too heavy. A heavy touch will strike the keys too sharply and cause them to cut the paper.
It is very largely by the setting out of the work that an expert typist may be linown from an inexpert one. Such matters as margins, spacing, and good paragraphing make all the difference to its appearance.
Margins and Spacing. Tho width of the margin depends very much upon the lind of work in hand. For literary work, official reports, or legal work the margin sliould be wide, varying from $1 \frac{1}{2}$ to 2 in . Letters usually look well witlı a good margin, but this will vary with the taste of the person writing.

It may be laid down as a fairly safe rule that it is better to err on the side of wide spacing. Single spacing may do for long business letters, for extensive cjuotation in the body of another work, and for one or two similar matters; but for ordinary clearness, as required in literary work and the like, double or even treble spacing is the best.

All paragraphs should be marked or in dented by taking the line several spaces inward, five being the usual distance. In official work it is well to double the space between the last line of the preceding para graph and the new one, in other words, to miss a line. This makes for clearness and heightens the effect of the paragraph. In addition, the typist should remember to leave one
opace after a conima, two after a colon or cemi-colon, and three or more after a fullpoint. Long quotations, as already mentioned, may he done with single spacing. They should also be indented to add to the effect.

In numbering pages, the number may be put in the centre of the top, enclosing it either in brackets or ly a dash on each side; or it inay be put at the bottom of the page.

A two-colour ribbon can add greatly to the finish of the completed work. The title may be underlined in red, or typed in red and underlined with the black or purple of the other half of the ribbon. Numbers look well done in red, and a red capital !etter to start the matter is also effective. On the other hand, the twocolour ribbon is by by no means esscntial for ordinary work, though it may be wanted for special work, such as plays.
Duplicating. If many copies of the same manuscript are required, tlicy may be produced either by means of carbon paper or hy cutting a stencil and using one of the many duplicalors on the inarliet. The former method is simple; the number of copies done at a time depends on the sharpness of the type, the thickness of the paper, and the lind of machine. It should be possible to do at least half a dozen good copies if thin paper is used. A layer of carbon paper is placed between each sheet of typing paper, and the whole is then inserted into the machine so that the face of the cartuon is away from the typist. Care should be taken to insert them evenly, in order that the lower shcets should be straight.

For stencil cutting a special waxed shect has to be procured. The ribbon is then removed and the copy typed with the bare type. This cuts the letters nto the wax shect, which can then be used as a stencil and rolled off on the duplicating machine to any quantity requiral.

TYPHOID FEVER. Typhoid fever. which is also known under the name of cuteric, is an infectious discase that occurs mostly in the last quarter of the year. Infection may be conveyod in drinking water, milk, ice, salad, celery and other uncooked vegetables. also through ovsters taken from beds that have become polluted by sewage.
The symptoms develop, from two to three weeks after exposure to infection, and during that time there may be no susjicion that anything is wrong. There may be, however, constant headaches and abdominal pains, with a steadily rising temperature until the patient becomes too ill to get about.

About the scventh day the rash ajpears in the form of rose-coloured spots on the chest or abdomen. In the second week the abdomen may lee swollen and the patient lies in a semiunconscious condition. During the third week the loss of fesh and strength is less marked in a favourable casc. Convalescence should begin with the fourth weck. One attack usually protects from future attacks.
Many complications may develop in typhoid. Two of the most dangerous are haemorrhage and perforation of the bowel, which are not uncommon and occur oftenest after the second week. A warning sign of blecding is a sudden increase of weakness or collapse, followed by a drop of several degrees in temperature.

During an epidemic or when typhoid occurs amongst people who are all using the same milk or water supply, it is only common prudence to submit to inoculution with antityphoid vaccine.
All drinking water and milk must be boiled, and every precaution taken to protect food from Hies, which are notorious carriers of infection. Cups and dishes used by the patient should be kept in the sickroom and never used by other people.
The patient's bed linen, towels, etc., should be soaked for 24 hours in a pail con-
taining $n 1$ in 20 solution of carbolic acid or other disinfectant and then they should be laundered separately. The excreta of the patient should be conptied into a closed vessel half fall of carbolic acid, $]$ in 20 , and allowed to stand for two hours before being emptied.

The nurse should scrub her hands with soap and a nail brush and soak them in a solution of one part of perchloride of mercury to 2,000 parts of water before going to her meals.

Efficient nursing is nll-important, by night as well as by day. Milk should be the main lood until well on into convalescence, but the patient may have as much water or fresh weak lemonarle as he ikes. During convalescence strict attention must be pail to dict.

After convalescence a person may continue to carry typhoid bacilli in his system. Such a carrier of the discuse is a danger to the public, especial!y if he hundles inilk or other food. It is his obvious duty to refrain from handling the food or food utensils of others. See Convalescence: Fever: Infectious Jiscasc.

TYPHUS FEVER. Typhus fever describes an acute, very contagious fever, usually coming on suddenly, causing great prostration and severe nervous symptoms, marked by reddish rash and terminating by rapid fall of the temperature (erisis). Formerly common amoug poorer people, it is now extremely rare. The infection of typhus fever is carried by lice.
Whenever possible, a person suffering from the diseasc should be taken to an isolation hospital. General treatment is set down under the headings Fever and Infectious Iisease.

UFULELE. This musical instrument is really a small guitar. It has four strings, and is played by plucking them. It was introduced into Britain and the United States after the Great War from the Hawaiian Islands, and was used with dance and ja\%\% music. See Guitar.

ULCER. A sore that involves the true skin or sonctimes the mucous membrane is described as an uleer. It is kept open and extends by the death of minute particles of tissue which are liquefied and removed in a discharge. Many different types of uleer are described, but each consists of an area more or less depressed below the general surface of the skin or mucous membranc, which is known as its floor, and around this a margin, or edge. From the surface of the ulcer there exudes a discharge which may be purulent or watery and profuse or scanty; sometimes it is mixed with blood.

As regards causation, ulcers fall into threc main groups, namely, those due to mechanical, chemical or septic irritation, those clue to specific micro-organisms, such as the tubercle bacillus and the spironema of syphilis, and those due to malignant new growths.

A trophic, or perforating, ulcer is one that occurs in locomotor ataxia, diabetes, or some other condition in which there is disease of nerves. An ulcer of this kind is quite painless.

The treatment of an uleer depends on its cause. In the treatment of ulcers belonging to the first group the main considerations are rest and cleanliness and, where necessary, the removal of any constitutional factor in so far as this is at all possible. Commonly, an ulcer can be cleaned up by applying boracic fomentations. Each tinc the fomentation is taken off the ulcer should be washed with an antiseptic lotion. An alternative treatment is to apply lint smeared with boracic ointment.
To obtain healing of varicose ulcers it is necessary to support the limb by applying a pure rubber bandage, a woven elastic bandage or a crêpe bandage. The pure rubber bandage is liable to cause irritation by imprisoning the sweat. A useful application for varicose ulcers is found in Unna's piste. When the uleer has healed it may be desirable to operate for the cure of the varicose vcins. See Antiscptic; Gastric Ulcer: Varicose Vein.

## UMBRELLAS AND THEIR REPAIR

## Smartness and Utility Combined in This Protective Device

This article, after some information on umbrellas in peneral, descrites in detail, with the aid of illustrations, the methods of reparing a damaged one. Sec Hall Stand; Walking Stick
While the choice of an umbrella may depend to some extent on the prevailing fashion, there are two factors, the ribs and the cover, which should always reccive careful attention.

The size is determined by the length of the rib, which varies between 24 to 26 in . for men, 27 to 36 in. for golf or carriage umbrellas, the usual length of rib for a woman's, short-sticked or "chubby" umbrella being 18 to 20 in., and for one with a full-length stick 21 to 23 in . The ribs may be fluted or solid, the latter being cheaper, and of course heavier, but not always so strong. Generady it may be said that an umbrella with solid ribs is a cheap class of article. Paragon or fluted rilos are made from a strip of stecl bent to a U-section, the curve of the $U$ being arranged to come next the cover in a sinished umbrella.
Five types of material are used for covering umbrellas: alpacas or dagmars, levantines, glorias, artificial silks and mixtures, and pure silks. In addition to their buli, alpacas, and more especially the cheaper varieties, have a coarse texture. A good gloria wears well, but many so-called glorias, which ought to be a mixture of silk and wool, contain a large percentage of cotton. Artiticial silks and mixtures have a glossy appearance, but are comparatively harsh in texture. Sill: always looks better than anything clsc, but a mixture of silk with cotton or wool should be chosen for durability, since silk covers have generally a tendency to split.

An umbrella ought not to be kept rolled up when not in use, otherwise splits and rents
are sure to result. After being out in the rain it should be allowed to stand or hang, handle downwards, until dry. If the moisture is not allowed to drain away from the ribs in this manner, rust and broken joints will ultimately be the consequence.

To roll an umbrella neatly, shake out the cover, gather the ends of the rilss in the left hand : pull cach fold into place, and, grasping near the bottom with the right hand, commence to roll. After fastening the elastic, roll again, and pull each fold taut if any looseness collects. If the elastic is worn, replace it with 6 in . of narrow black hat clastic.

Silver and metal collars and bands are fixed to the stick by means of a mixture of weak glue and plaster of paris. A special caplilling cement, obtainable from the wholesalc manufacturer, is used for fastening on knobs and caps. A little of the cement is melted and poured into the cap, the stick being inserted immediately, as the cement sets very rapidly. Only a little coinent should be used, or the stick will not go home.
Umbrella Repairs. The two repairing operations most usually necessary are mending or changing the cover and replacing a hroken rib. Neither of thesc operations should offer any real difficulty.

When repairing a broken rib care should be taken to see that the new rib is of the same type as the others, and that it and its stretcher are exactly the right size, otherwise it will be left projecting or will close before the rest, as the
case may bc. If it is only the stretcher that is serve if the wood or composition cap on the in enany forms of construction the rilos broken, a strctcher taken from a broken rib can he used to repair it. Take off the ontside cap, by punching out the rivets and withdrawing it, as shown in Fig. 3, then unwire the rumer and turn the umbrella inside oint. Before doing this it is better to unstitch a couple of the corners from the ribs; this will guard ngainst splitting the cover or breaking another rib. To turn the umbrella inside out, stand with it partly open, the stick passing between the left arm and the body, the inside of the cover resting against the left side, but outside the left arm, and pull with tho right hand.
A rivet will be seen in the joint between the stretcher and the rib. The head of this should be filed off, and the rivet punched out, a
 bit of spring wire. The new stretcher must be exactly the same length as the old one, and it should be fitted so that its hollow side is towards the handle when the umbrella is open. The taper cap should be replaced and carefully riveted to the stick. The same process of turning the umbrella inside out and measuring carefully must be adopted in the case of a broken rib, but here it will, in nddition, be necessary to unpick the stitches on the broken rib and remove it entirely. If it is only the cye of the rib which is broken, it is only necessary to replace the top tip. The new tip is measured along the rib, the broken end cut off at the right spot, and the tip knocked on, taking care not to close the cye.

If a small slit occurs in the cover, an effective method of repair is to obtain a small piece of black silk, or other material similar to the covering itself, and, after opening the umbrella, carefully stitch the patch on the inside of the cover, commencing on one side of the slit first. The slit is drawn together with $n$ fow tacking threads, and the patch neatly sewn all round. The trekings are then removed and the stitches caught together, and to the patch, with a few threads. Any danage to the fastenings of the cover at the outer ends of the ribs can be remedied with ordinary black cotton. A few turns are sewn into the cover at the point or apex, the needle is passed through the small hole or cye on the end of the rib, the cover drawn tight, and a few stitches are then passed through the eye on the cover.

When the liandle breaks, its mode of repair will be determined ly the material of the handle and of the stick. Many umbrellas are made with composition handles and wooden sticks, and the hnndle sometimes becomes loose. To refix it the end of the stick is smeared with liquid glue, a fow strands of cotton twisted round it, and the handle pushed on. The same procedure will
 To make a secure joh of a handle it may he riveted on after the glue has set hard. The liandle may be grasped in the vice, as in Fig. 1, the other end of the umbirella being supported on a block. A very fine hole, about $\frac{1}{10}$ in diameter, is drilled through the handle and the stick: the two ends of the hole aro slightly countersunk, and a small piece of brass wire, which should fit nicely in the hole, is pushed through it. The two ends can thes be cut off about it in from the handle on each side and riveted any surplus that may project being filed away, as in Fig. 2. To avoid scratching the handle, a piece of card or tin should be wrapped around

fit into little slots cut across the grooved ring formed on the end of the runner. The ends of the ribs have smal! holes through them, and if these ribs be inserted through the slots the holes will register with the groove on the runner. A wire is threaded through the holes, and the ribs are drawn into the groove on the runner, thus forming a kind of hinge pin for each of the ribs The operation pictured in Fig. 4 is that of cutting this wire so as to relcase the stretcher or stay, this being the strut-like portion on the rib which connects with the runner at one end and about the middle of the length of the rib at the other. The umbrella is opened and turned inside out, using the method earlier described, and the stick and ribs are brought into line. This provides access to the top cyes, that is, the little joints in the notch neal the end of the stick.
The cover is then entircly stripped from the ribs, and if the latter are rusted they may be cleancd by rubbing them with emery paper and then reblacked. They should bc sct aside to dry thoroughly hard. and are then refixed to the top notch. This operation is illustrated in Fig. 5 , and is accomplished by first arranging all the ribs so that the stays all point in one direction, and a piece of tying wire, which may be of tinned iron, is bent through the top eyes. The wire is twisted around and the ribs pushed on it until the wire is in more or less a U-sliape.
The first few ribs are inserted in the notch, taking care to note that an additional small notch is generally cut at one point, and is intended for the reception of the twisted end of the tying wire. Consequently the first pair of ribs shou!d be inserted into the slots opposite to this notch. The others are pressed into place, as shown in Fig .5 , and finally the wire is drawn tight and twisted back with a pair of pliers, the surplus being then cut off and the ends of the wire pressed into the little noteh.
The ribs have now to be opened to ascertain that all the stays point towards the handle, and to ensure that none of them have been inadvert ently fixed the wrong way round. If so, the process is repeated and the fault remedied, after which the runner is replaced. The muffles. that is, the little picces of black material which are stitched to the ribs to prevent friction of the ribs wearing away the cover, are examined to sec that they are in good condition : if not, they should be replaced by new ones. They may be any black material, but are preferably the special waterproof oval muffles which only require sewing in place. The niethod of fixing is by stitching them around the ribs.
The next step is to fit the cover,
it immediately above the rivet, as shown. This prevents the filc coming in contact with the handle.

Re-covering. In the re-covering of an umbrella several processes are involved, and the amateur may find it difficult to make an efficient job the first time, but care and a little patience will ensure a tolerably good result, as can be judged from the accompanying illustrations. The first step, as illustrated in Fig. 3, is the removal of the tapered cap covering the outside of the notch ring which supports the rilis. The stitches on half of the tips of the ribs are cut away with a sharp knife, thus releasing the cover in readiness for the next operation, which consists in removing the wire which holds the ribs to the runner, the tubular momber which slips up and down the stick, shown in Fig. 4. the size depending, of course, on the length of the ribs. The cover can be obtained ready made. or, if preferred, can be made up at home. Assuming the cover is bought ready for use, the stick is inserted through the hole in the centre of the cover, this being accomplished while grasping the whole of the ribs in the left hand and supporting the cover with the right. To prevent the cover from splitting, it is stitched with waxed thread around the hole where the stick comes through. The cover should be stitched in two or three places to each of the ribs in turn. It is then worked into place at the corners and seamed parts and drawn to the top of the ribs by passing u thread through the cover and fastening it, passing the needle through the top eye, thus drawing the cover upward and firmly sewing it. The cover is sewn to each rib in
the same way taking carc to draw it well into place before fastening the top corners.

A small rosette is sewn on the outside of the cover to protect it from the ehafe of the taper cap on the outside, which is then fixal in position nnd sccured with a couple of small pins. A rosotte should also be stitched round the runne: near to the ribs to precent it chafing the fingers while opening the umbrella. The umbrella can then be tested, and if properly covered should open uniformly and conveniently. A new tassel or loop may be a.tded if desired.

The forcgoing is a general method of re-covering an umbre!la, and will enable moat patterns to be dealt with. Sunshades may le treated in the same way. Some particular malies of umbrella are rather ilifferently arranged, and may ca!! for modification in the trcatment.

The short umbrella used by women has $n$ cap to match the handle, in mood. glass or some composition and the stick fits into a socket formed in the cap. The cap is usun!ly cemented on, and must be carefully loosened and eased off the stick before turning the umbre!la inside out to get at the top cye. The end of the umbrella may be hedd in a jet of hot steain to loosen the cop, or a little of some spirit solvent mighit be careful!y poured into the joint to dissoive the cement. Since some of the compositions used for handles and eaps may be of an inflammable nature, it is necessary to use great care in applying heat to them. In refixing these fittings the ends of the stick should be roughener to allord a grip for the cement. Shonld the slick fit too loosely into the socket, $\Omega$ few threads of cotton may be twisted round the former after coating it with cement.

UMBRELLA FERN. This is a popular name of the greenhouse fern, gleichenia. Of slender climbing growth, it is very ornamental when trained to cover a wire trellis or sticks. The plants should bo potted in a compost of loam, peat and leaf-mould, with sand added frecely, and they should be provided wit! ample drainage of clean crocks. A temperature of 50 degrees is high enough in winter, and care must be taken not to over-water them at that season. Plants may he propagated by spores, or by selected portions of creeping stems to which roots are attached.

UMBRELLA PLANT. This is the common name of an ornamental greenhouse plant, Cyperus alternifolius. It is easily grown in $n$ temperature of 5.5 to 60 degrees if potted in sandy loam and leaf-mould; the soil must. be kept thoroughly moist. Propagation of the umbrella plant is effected by division or by laking off the tops of the stems and inserting them as cuttings.

UNCONSCIOUSNESS. It is very im. portant when a person is found in a state of unconsiousness to ascertain the exact cause of his condition. Mistakes are frequently made, with scrious consequences to the patient. Thesc errors occur most cominonly when the unconscious person smells of alcohol This suggests drunkenness; but the causc may be apoplexy, a fractured skull, or somic one of a dozen other abnormal conditions.
The following are the principal canses of unconsciousnass: Fainting from temporary weakness of the heart : apoplexy, due usually to bleeding into the brain; epilepsy following the fits: concussion of the brain caused ly a fnll, etc.; compression of the hrain, the result of a depressed fracture of the skull and other causes : heat stroke or the effects of cold : meningitis and other forms of brain disease; asphyxia due to gas poisoning or other causes ; electric shock ; hysteria, in which the loss of consciousness is seldom complete : catalepsy and trance ; internal poisons, as in diabetes : external poisons, such as morphia, chloral, etc.

In stupor the patient can be aroused for a moment by speaking very loudly or stimu lating him in some way.

Sometimes the person appears to be unconscious when he is not so, but only in a weak and dazed condition. A simple test to apply in this case is as follows: Raise the upper eyc lid by pushing up the cyebrow with the index finger. Then most gently touch the eye with the tip of the second finger. If the person is unconscious, the eye remains open; if he is not wholly unconscious, he winks more or less nud the cye closes.
'Treatment will depend chielly on the cause. In ascertaining this certain observations should be made. Note any evidence of $n$ struggle or indications of an accident. If any bottle is near the palient, this and any vomited matter should be preserved for examination by the doctor who has been summoned. It should be remembered that when the smell of alcohol is found it may only signify that the patient drank some whisky when he found a fit coming on, or that, though he had taken alcohol, even more than was good for him, the unconscious. ness may really he due to fracture of the sku! sustained in a fall or to some other scrious cause. Whenever there is the siightest doubt, the person should be treated on the assumption that he is ill.

Unless the cause is clearly known, it is better to lieep the patient perfectly quiet until n doctor comes; otherwise serious injury inay be done by adopting wrong treatment. The

Underpinning. Fig. 1. General disposition of shores and truts for underpinning operations
carving a sirloin it is customary to begin with the undercut, which will often suffice for a small bouseho!d, leaving the more substantial part of the sirloin to be caten cold. Sometimes the underent is removed before the joint is cooked and is served separately as a hraised dish or grill. See Beef; Carving; Fillet; Noisettc: Sirloin; Stcak.

UNDERLAY. This word is used for the material that is placed benenth carpets and other lloor coverings to malic them wear longer and to improve their feel to the fect. Felt of a coarse kind makes the best underlay for pile or hair carpets. Another underlay is felt paper, which can be obtained up to 60 in . wide. Cedar felt is a paper of this kind. It contains disintegrated cedar wood, and holds the aroma of this wooll for years. It is, therefore, an excellent antidote to moth Coarse canvas makes a good underlay. A waterproof underlay, which gives a soft tread and is suitable for linoleum and other lloor coverings, prevents board marks and is inexpensive. See Carpet.

UNDERPINNING. The act of supporting a wall, the lower part or foundations of which are defective, and the huilding up of new solid work for the wall to rest upon is known as underpinning. Underpinning is sometimes necessary owing to the subsidence of the foundations, a common example heing the failure of a bay window or other construction.

Essentially, the operation comprises the shoring up of the building to prevent it falling ; the provision of local supports to take tle weight of the wall above the portion affected: the removal of the old wall and foundations. and the construction of the new work.
Underpinning is resorted to also when it is desired to nake some alteration to the lower portion of an existing building which would necessitate the removal of the main structure at tho base. If, for example, it was desired to insert a shop front into what was originally a blank wall, or construct a cellar under an existing building, underpinning would have 10 be carried out. The materinls used ate principally timber of rather large size and of good quality. For the insertion of $n$ shop front a girder or bressummer is placed across the opening to carry the weight of the building above the window, and the weight of the building has to be supported while the girder is built into position. To clo this it is neccssary to erect a raking shoring. to provent the building falling outward, and for this also timbers arc necded. Ncedles are first placed into the wall. these being made from picces of 4 by 3 in timber. They are placed in holes cut into the wall to a depth of 4 to 6 in . and project beyond the face of the wall alout 9 in .

Over the needle is placed a walling piece, that is, a piece of timber 9 in . liy 3 in . of the length required in the particular casc. A mortise or hole is cut into this walling piece sufficient to let the needle pass through the piece, which is placed lengthways to the vertical of the wall. A noteh is then taken into the needle level with the face of the walling piece placed over it. This notch receives the raking as comfortable as possible, and covered with shore, which is cut so as to fit into it, and blankets or any warm article available. He extends from the wall to a solid base in the should not be raised into a sitting posture. See Apoplexy ; Artificial Respiration : Asplyxia : Brain; Bright's Disease; Catalepsy; Epilepsy; Fainting; Gas Poisoning; Heat Stroke; Poisoning: Uracmia, etc.

UNDERCUT : Of a Sirloin. The undercut or lower portion of a sirloin is also known as fillet of becf, and, while usually of small size in proportion to the upper part, it is considered by many to be the prime part of the joint. In carving, the undercut is carved vertically or at right angles to the upper part. It sliould always be eaten hot, and consequently in
ground. The needle is further strengthened by nailing a cleat above and against it, a cleat being a piece of wood cut out of 4 in . by 3 in. stuff and 9 to 12 in. long.
The piece of timber forming the raking shore may consist of 7 or 8 in . square stuff eut to the length required. The raking shore being firmly fixed lateral support is ensured. The number of raking shores depends upon the size of the opening that is being made, and they are spaced as stated for the needles. The interior of the building has also to be considered, and a vertical strut has to be placed between the
 arranging support while making alterations to damp coursa
floor below and the ceiling above. This strut is formed of 4 by 4 in. stuff, and is sccurcly werlged top and bottom.

Now it is necessary to arrange to takethe weight of the wall, that is, to erect the underpinning proper. A sufficient number of holes are cut through the wall to allow other needles to pass through. These needles are of a larger size than thoso previously mentioned, not less than 9 in square. They are put right through the wall and arc supported in turn by stanchions of the same sized naterial as the needles, the stanchions resting on sole plates that are placed on the ground. Thesc timbers are then werlged tightly into position: they are strutted and cleated as may be necessary, and generally arranged as shown in Fig. 1 on the previous page
When sufficient of these for the size of the opening lave been erceted, the work of making the opening is procecded with. The girder or bressummer is placed in position and built up, and, when properly set, all of the timbers crected to carry the weight are gradually renoved. A similar procedure is followed in forming a cellar, but the work is rather inore complicated. The large needles are placed at a height that will just clear the position into which the girder, etc., is to be placed.
A form of underpinning often necessitated by the failure of the damp-proof course consists in removing a couple of courses of brickwork from a wall, inserting the damp-proof coursc, and building the wall up again. Providing the wall is sound and well built and that the bricks are removed carefully, it is generally possible to carry out this work with no. particular support except at such places as the brickwork beneath a window opening, or under the support of a particularly heavy part of the building. The work may be locally supported in the manner illustrated in Fig. 2, by placing a short, stout timber through the aperture and resting it upon a couple of built-up timber supports, so as to relieve the wall of some of the weight imposed upon it. See Brick; Concrete; Danip Course; House.

UNION CLOTH. Cloth made half of one material and half of another is known as union, and is usually cheaper than the goods which it imitates. Union wool clbths are partly cotton. The cotton threads are generally concealed by the woollen ones, and are ordinarily the up-and-down and not the cross wise threads.
 for glass cloths as pure linen. one shaft to a nother at an angle to it, but their present wide use is due to the development of the motor car industry. 'They have been generally cmployed on motor vebicles for a number of years to give Hexibility to the propeller shaft by which power is transmitted from the ellgine and gear box to the
rear or live axle; rear or live axle;
when so applicd they are often terned Carclan joints and the propeller shaft is often termed a Cardan shaft.

The simple bal! and-socket joints used so largely in stecring con nexions and the controls of motor cars do not transmit rotation and, although they are not usually termed universal joints, an cxample will be described later.

The earliest universal joints were known as Hooke's joints, after their designer, and were constructed on the principle illustrated in Fig. ]. Each of the two shafts carries a fork on its end and the forks are connected by an intermedial member, in the form of

Dniversal Joint. Figs. 1 and 2. Examples of common types of nniversal joint. Fig. 3. Principal component farts of a nniversal joint as used in the projeller shaft of a motor vehicle. For details see text. fig. A. Hardy dist joint. Fig. 5. Ball centre support for shalt

Union cloths are preferred for certain pur- a cross or star. The arms of the cross pivot poses. Union flannels, for instance, are lcss in the ends of the fork, and very little considerinclined to shrink than all wool. Union ation will show that the two shafts can easily linings are neater than all-wool and warmer inove out of alinement, but that they will than all-cotton linings. Union blankets are always rotate together. In another form of cheaper than wool blankets, and the better this joint shown in Fig. 2 the cross is replaced qualities of union blanket are superior to the by a ring, but the action is the saine.
poorest of the guarantecd all-wool kincl. Joints of these designs, although satisfac. Union linen is half cotton and usually not so tory for many purposes, require some modilicastrong as pure flax. Union linen is not so good tion before they can be used on motor vehicles,
for glass cloths as pure linen.
in vicw particularly of the exposure of the

UNIVERSAL JOINT. For nearly threc transmission to mud and dust, the high specd centurics universal joints have been occa- of working, and the power transmitted. They sionally used to transmit rotary movement fiom are, therefore, properly enclosed and carcfully

Fig. 6. Left, sectional view of a rubber disk type of unaversal joint with ba! centreing arrangement. Right, details of the disk lubricated, an example being afforded by the widely used Hardy-Spicer joint, the various parts of which are shown in Fig. 3, as applied at the forward end of the propeller shaft and at the rear end of the gear box.
The intermediate member, C , is pivoted both to the driven fork, $B$, and to the driving member, A. The latter comprises two pivot lugs on onc face of an annular disk which is bolted to a disk, D , fixed to the end of the gearbox driven shaft. The driven fork is formed with a long splined boss engaging the forward end of the propeller shaft so as to allow a small amount of sliding movement which results fron the up and down movements of the rear axle. The joint is enclosed in a hemispherical cover in two parts, of which one part, $\mathbf{E}$, is bolted to the driving disks and the other part, $F$, fits on the boss of the driven fork, but is pressed up against the first part by a helicai spring. The method of pivoting the interinediate member, C , to the fork and disk is interesting and ingenious. Between each pin on the member C and the open-sided hole in the other part is introduced a hard steel hush, G, which is pushed into position inwards, the four bushes being held in position by spring rings and hy the hemispherical cover. The hush is thus held securely in the recess in the fork.
The joint should be refilled with special non-separating grease after about every five thousand miles run.
Owing to the high speed of rotation the lubricant is impelled by centrifugal force towards the outcr part of the casing close to the pivots which form the principal working parts. The pressures on the pins are very liigh and any shortage of lubricant may bring about excessive wear.
Other Types. Another type of miversal joint which has been widely uned on notorcars employs a reinforced rubber disk or ring
to obtain Hexibility. Fig. 4 shows diagrammatically a light form with a two-armed spider fixed to the end of each of the shafts to be connected, this pattern being sometimes used for auxiliaries such as the magneto.

Joints for propeller shafts are constructed with threc-armed spiders, as shown in Figs. 5 and 6. The opposing arms alternate with one another and are connected by bolts to the rubber disk or annulus, which is made of solid rubber with a number of layers of coarse faloric embedded in it. The fabric renders it practically incxtensible, so that a heavy drive can be transmitted, while leaving it quite flexible.

Universal Joint. Fig. 7. An example of a ball joint as used on the steering drag link on a motor car

In this type of universal joint the rubber disk may distort so that the two shafts will not be maintained strictly in line, in which casc one is bound to run out of truth with consequent vibration. To avoid this, the self-centring construction shown in Fig. 6 is adopted. The driving shaft carries a ballshaped extension, $K$, which fits in a cylindrical socket in the driven shaft, the ball being in line with the rubber ring. The two spiders

## UPHOLSTERY AND UPHOLSTERING

## How the Amateur can Save the Cost of Repairs

This contribution describes in detail how various articles of furniture can be upholstered at home. Reference may be suggested to the entries in this work on the articles themselves, eg. Armciair; Chair; Chesterfield; Poufe; Sofa; and to those on the materials, e.g. Amcrican Cloth: Chintz; Cretonnc; Horsehair; Tapestry Needlework; Weaving. See also Colour and the entries on the various rooms, e.g. Drawing Room; Sitting.Room

This article explains with the aid of the illustrations how to cover a plain seat, a sprung seat, and a fully upholstered divan easy chair, thus covering practically the whole range of the upholsterer's eraft, with directions for the subsidiary branch of cutting and making loose covers

Upholstering consists chiefly in stuffing, covering, and re-covering furniture. The materials and tools required are by no means expensive ; those uscd for the coverings are perhaps the most costly.

The most beautiful and durable covers are hand-made. They may be of hand-woven silk or tapestry, or they may be of tajestry needlework on canvas, which is cut to fit the chair or other piece to he upholstered, good turnings bcing allowed before the design is embroidered in wools, colouring and patterns being chosen to suit the frame and room. Needlework coverings can be adapted to modern pieces, but are most suitable for re-covering antique chairs or reproductions of antique styles.

Hand-woven fabrics can be produced in a variety of stripes, sma! patterns and shot effects in wool, silk or flax fibres, separately or in combination, and many variations are possible with a simple setting up of the loom. One piece of furniture can be covered in such fabric, or a whole set of chairs to match, with excellent results if due regard is paid to colour and weaving.

A great deal of work is carried out with machine-made tapestry, which may be woven sither from cotton, silk, artificial silk, wool, or a mixture of either. Ordinary upholstering tapestry varies in width from about 48 to 52 in . and is thu economical for cutting. It can be obtained in a variety of patterns and

J, L, may both be fixed permanently to their respective shafts; that is, a splined connexion need not be cmployed since the rubber ring and the ball joint will allow some end play of the shafts. This type of joint is silent under all conditions and only the ball connexion requires lubrication. Care must, in fact, be taken to avoid oil or grease on the rubber, which would in that case become soft and useless. Petrol, if uscd at once for cleaning, will prevent trouble.

The axes of the two shafts connected by a universal joint should always be as nearly in alinement as possible, both to resist wear and also, in the metallic type, to avoid irregularity in the running In this type if one shaft rotates uniformly the other will be slightly accelerated and retarded twice during each revolution, and this periodic variation of speed, together with the accompanying loss of power, increases as the angle betwcen the shafts increases.

The simple ball-and-socket joint forms a most useful conncrion since it allows frecdom of movement in all directions, but without slackness. An example as applied to the ends of the drag link on a motor car is shown in Fig. 7. This link connects the stcering gear to the axle, and it is, therefore, continually llexing. A ball on the arm works between two sockets which are held in position by a strong helical spring. The screwed plug which in this case forms one of the sockets and compresses the spring must always be locked in position by a split pin. The ball and the sockets are usually case-hardened and regular lubrication with grease is necessary. Small joints of similar construction arc often used on motor car controls.
colours, and is thus adaptable to all forms of decoration Many of the finest designs are in artificial silk mixtures
Tapestry of good quality is expensive, and it is therefore important to choose a design which will cut to the best advantage. Thus, if the selected pattern has a marked feature, such as a cluster of flowers, which is only repeated every 50 in ., obviously this should appear in the centre of the bacli or scat of the chair. To obtain this result, especially if only one or two pieces of furniture are to be covered, would mean a considerable amount
of waste, consequently it is better to chnose a simple all-over style of covering. The same difficulty has to bc coped with in damask. another excollent upholstery fabric.
A material in extensi ve use is velvet, in 50 in width, and obtainable in many colours. Plush is also used but has not the same rich effect. Other materials inclucle mohair fabrics in plain colours and checked designs. rep, chint\%, and cretonne, the latter a braided cotton fabric, much cheaper but less durable than tapestry.

Good leather upholstery is suitable for dining-room furniture. Leather, particularly moroceo or pliable goat skin, is dyed in many colours and finished with a grained or bright surface. It is obtainable in the form of slins of irregular shape, ranging from about 22 by 26 in . in the smaller ones to about 30 by 35 in. in the larger. As the leather has to be stretched in upholstering, even minute blemishes are speedily revealed. Other leathers include the hides or cow-hides, which are cheaper than morocco and obtainable in fairly large skins.

## Leather Substitutes and Ornamentation

Many excellent leather substitutes are on the market with various trade marlis and branded names, among which may be mentioned pegamoid and rexine. Most of these are woven fabrics covered with a waterproof material and closely resembling leather. Oil baize, or decorene, of British make, is another fabric of this class which is often used. Among the various forms of ornament for coverings are the gimps or strips of tape-like material for edging, fringes and cords, brass-headed and other tacks, and buttons, which may have a covering similar to that used in the upholstery

Most of the tools required, illustrated in Fig. 1, will be found in the avcrage lome, an exception being the webbing strainer. The upholsterer uses a special form of light hammer, called the cabriole hammer, but the more common one illustrated will serve for most jobs
The webbing strainer is a pair of pliers with wide jaws or flanges. One of the jaws has a broad projecting portion which engages the side of the chair, while the webbing is gripped between the jaws: the llanged portion rests against the side of the chair, and the handles are pressed downward, thus, getting a leverage on the webbing.
The other tools include a strong pair of scissors and a small chisel, such as a carpenter's old firmer chisel, with a nallet to drive it. A rasp, tape measure, and rule are also needed, and preferably some sort of low table or stand whercon to rest the work. A selection or needles is required, and several are show

Upholsterg. Fig. 1. Necessary tools and equipment, including webbing strainer, ncedies of various shapes, tacks, scissors, hammer and chisel, also chain springs, webbing, canvas, and stuffing materials

fastened into a piece of material in which they are rolled when not in use. The selection should include two or three upholsterer's packing needles, which have two points, ordinary packing needles, and a regulator. The latter is a piece of steel from 6 to 18 in . long, and tapered at one end to a fine point, the other having a flattened portion. The pointed end of the regulator is inserted into the stuffing material while the operation of stitching is in progress.

The flattened end of the regulator is used in buttoned work, and also for tucking away any odd ends of stulting or fabric The needles should range from 4 to 12 in . in length In difficult cases it is desirable to use a semicircular as well as a pattern known as a spring needle. This latter type of needle is straight for some three-quarters of its length, while the remaining portion is curved. Some needles are made with bayonet-pointed ends, so as to cut cleanly through the covering material.

The amateur desirous of taking up uphol. stery work should start with some simple operation such as re-stuffing and re-covering a chair Broadly speaking, there are two methods of upholstering. In one, the chair seat or other part of furniture is simply padded with some suitable stuffing and the exterior covered with the desired tapestry or other fabric. 13y the other method, upholsterer's springs are used to give resiliency to the seat, etc. The springs illustrated in Fig. 1 are spiral or coil springs. They are made in various sizes, and can be obtained from any furnishing ironmonger's.

Webbing is one of the most important of the unaterials employed. It must be made of very strong braid, and only a really good quality should be purchased. The hest qualities are macle of flax, and are sold in pieces about 18 yd . in length, the width varying from 1 in. to $2 \frac{1}{2} \mathrm{in}$. The webbing has to be thoroughly stretched before it is used. One method is to suspend it by looping it over
stout bars hung from the ceiling and hanging known as fibre, which is a species of fine cord, heavy weights on the lower ends of the is often used as a substitute for horsehair, webbing.
Hessian, a lind of canvas woven from jute or hemp, and sometimes known as spring canvas, is used for the coverings of the tops of the springs. Scrym, a light canvas with an
 open mesh, is employed to keep the padding springiness, besides being excoptionally clean on top of the springs in its proper place and sanitary. and shape.

A great deal of stuffing is carried out with
Special kinds of twine are required. Fine wool and flock, the latter being a waste product or stitching twine should be obtained for made from rag. Its manufacture is regulated sewing the edges of the scrym : spring twine, by Act of Parliament, which has the effect which is thicker, is used to fasten the springs of keeping it reasonably clean. Ordinary

Showing stuffing in place and second piece of canvas being tacked over it. Fig. 8. Applying the covering
to the webbing. The stoutest material is wadding is useful to the amateur for stuffing, often known as laid cord, and is used to tie and particularly as a covering immediately the springs down to the proper size and shape. beneath the outer covering of tapestry, etc. The webbing is attached to the framework by It imparts a smoothness to the finished work. tacks, which should be of the cut or fine A supply of the materials mentioned can be variety, and either brass or black enamelled. obtained from a good-class draper's or Proofed tin tacks are stouter and have larger furnishing house.
heads. Those about $\frac{5}{8} \mathrm{in}$. long should be used for fastening the webbing; others, from $\frac{3}{8}$ in to $\frac{1}{2}$ in., being utilized for tacking the canvas or other materials.
Materials for Stuffing. For the stuffing, nothing beats horsehair, the best being obtained from the tail and mane. In the treatment to which it is subjected it is cleansed and curled into ropes, the curl being the feature which gives horsehair its peculiar springy property. Inferior qualities are short in length and lacking in resiliency. A material

Re-upholstering a Chair. In re-upholstering an or linary chair the old coverings and webbing arc first removed. This is done by prizing out the tacks holding the gimps, tearing off the covering, removing padding and springs and finally removing the webbing by means of an old chisel and a mallet. If the chise! is pressed against the head of the tack and given a sharp blow, it will drive the tack from the wood. The chair should then be thoroughly cleaned, and, if necessary, any repolishing or staining carried out on the
framing, particularly around those noints adjacent to the upholstery, or where the upholstery will ultimately go. The resu t at this stage is illustrated in Fig. 2.
The first process in the actual re-upholstering is to take a pieee of webbing, fold over the end so ns to double it, and nail it to one side of the chair frame. The webbing is cut to length, which should he rather more than the width of the frame. The overhanging end of the webbing is grasped between the projecting jaws of the webbing strainer and the latter pressed downward with the left hand. The webbing is then sccured whilo it is atretched very tightly by driving a tack or two through it near to the inner edge of the framing, this operation being shown in Fig. 3. It is im portant to obtain the utmost levernge on the webbing so as to strot ch it as tightly as possible. The overhanging part is folded back on to the top of the webbing and nailed as in Fig. 4. It should be noted that when the webbing is arranged in this way the loose end is doubled under the webbing in the first fixing, whereas the second end is finished by being doubled over and tacked down on top of the webbing.

The remain:ler of the webbings have now to be fixcd. A common arrangement is that in lig. 5, two webs being arranged across the chair seat from side to side and three from front to hack. The webs should interlace with one piece alternately over and under the others, as shown, each of these webs being

Upholstery. Fig. A. Showing how the gimp is arranged round top of the leg and secuied by covered tacks
attached in exactly the same way as the first. A picce of the canvas has to be fastened to the framework, and old canvas may be used if it is in good cnough condi'ion. It is secured by folding the edges under and tacking it neatly to the framework, as in Fig 6 .

The seat can be padded with any of the materials mentioncd. In the example in Fig. 7 ordinary fock is used. This is worked between the hands to make it even and uniform. It should he distributed over the canvas and worked into the desired curvature of the linished seat, using more flock in the centre than at the sides. After the flock has been arranged, the second canvas or scrym is laid over the flock and tacked to the edges of the framework of the chair, as shown in lig. 7.
The material chosen for the covering must be cut to allow sufficient overhang on all four sides. It is then fixed to the front part of the chair frame, as in Fig. 8, by driving in a few tacks. The nover should be pleated neatly at the corners by folding the material so as to leave only one fold showing at the corner. The covering is drawn tightly and uniformly as the tacks are driven, and should bo neatly and carefully fitted around the tacking lines.

It is finished, as Fig. 0 shows, by trimming with gimp, secured with covered tacks. The gimp should be carefully worked all round to cover the joint between the covering and the frame of the chair, for which purpose the covering must be cut accurately.
Use of Springs. The method of upholstering a chair with springs differs considerably. In this case the webbing is applied to the bottom of the frame. The chair is first pre pared as already described. It is often p!aced upside down on a stout table or trestle, and the webbing applied to the underside of the frame, as in Fig. 10. Springs have to be sewn on to the top of the webbing. The usual plan is to employ three springs, two on the front part of the chair and one behind them centrally. They are sewn in place by stitch. ing through the webbing in three positions for each spring, drawing the twine tightly each lime and continuing from one spring to the other until this part of the work is completed. The method of stitching is explained in Fig. 11, where the fastening of the last spring is in progress. The necdle is thrust through from the top of the webbing with the right hand and pressed through with the left hand, and, when necessary, passed backward again from the left to the right. and so on until the fastening is quite completed.
The springs have next to be fastened with thick spring or laid cord, usually in the manner illustrated in lFig. 12. The springs are socured in such a way that the strings draw them down and slightly depress then. They should be fastened in the first place to each side of the framing, the strings being attached to taeks driven into the frame itself. Another string is used to connect between the front two and the rear spring, and the latter is secured by another supporting string to the back of the frame. The object of fastening the springs in this way is to prevent them from grinding or rubbing when the chair is in use and to keep then in place while the upholstering is in progress.
The purpose of compressing the springs at the start is to ensure that they will constantly exart a pressure between the lower webbing and the underside of the covering material,

Upholsterg. The varions atages in upholstering a spring chair. Fig. 10. Nailing webbing to underside of seat. Fig. 11. Sewing springs to webbing. and thereby keep the chair seat in its proper which is a twine worked around the outside of shape. The size of the springs is usually about the curved part of the canvas and caught to 6 in. in length and No. 8 gauge. The height of the set from the bottom of the frame to the top of the seat, when it is finished, should be about $5 \frac{1}{2} \mathrm{in}$. If the seat is to finish 6 in . from bottom to top, it is usual to allow $1 \frac{1}{2} \mathrm{in}$. for the thickness of the filling or stuffing, and therefore it is necessary to compress the springs by about $1 \frac{1}{2}$ in.
In placing the springs the finishing end of the coils should all point in the same direction, towards the front of the seat. The springs should always rest on two webs where they overlap each other. It is also neccssary to tie the springs in such a wny that their upper surfaces conform generally to the curvature of the seat or other part of the chair, and the springs must always be lashed in such in way that they can excrt their pressure in the same line as that of their own length, i.c. upwards and not sideways

## Covering the Springs

When the springs are fixed satisfactorily they have to be covered, in the manner show in Fig. 13, with a piece of strong canvas. This is first fixed to the back rail with a few tem porary tacks. The canvas is then held tightly and tacked to the front rail. The sides are tacked alternately : first with a tack near to the back of the chair on one side, then the canvas is pulled tight and fastened with tacks on the opposite side and so on until it is tacked all round. It must not be drawn tightly enough to depress the springs further, but should just lie evenly upon them. The tops of the springs arc sewn to the canvas with a spring needle by the method illustrated in Fig. 14. The needle is passed through the canvas and each spring sewn in three places, the string being worked continuously from one spring to the other, and finished ultimately at the starting point.
The method of applying the stuffing is illustrated in Fig. 15. Whatever material is used it must be picked or teased out into a loose mass, packed on and around the canvas. and built up as nearly as possible to the desired shape of the seat. To prevent the stuffing from moving, it should be fastened with a laair tie,
the stulfing by sewing at the corners. The string should be about 3 in. up from the frame, and there should be about 8 or 9 in . of space between each tie. This twine is left quite loose and is tightened up when all the stuffing has been worked in.
After the sides have been packed up tightly with stulfing, the centre is filled in and the whole arranged as smoothly and evenly as possible. The scrym has then to be applied to the whole so as to cover and enclose the stuffing, this operation being shown in a nearly completed stage in Fig. 16. The scrym should be of such a size as to allow for turning up on all sides. The first side to be fastened is the back, the canvas being temporarily secured with three tacks. The stuffing is lightly compressed with one hand and the scrym secured temporarily to the front rail. The scrym is an open mesh, the strands of which can quite easily be seen, and in fastening or tacking it down these strands should be kept as straight as possible. This little detail will prevent the risk of subsequent slackening, or at least minimize it.
The sides of the scrym are tacked to the frame, being turned in so as to reveal the edge. This being accomplished, the scrym has to be tied or sewn to the spring canvas with an 8 in. straight needlc. This is used with a tine twine and stitches are made by thrusting the needle through from a point at a distance of a few inches from the point which will form the edge of the chair, the start being made from one back edge. The point of the needle is worked through the stuffing, and emerges through the side of the canvas. To form the edge of the seat, twine is worked in a similar manner from the upper part through the stuffing and out at the side, as in Fig. 17, and drawn tight to form an edge or roll of stuffing. It is important that the line of this work be kept of good shape, as upon that will depend the appearance of the finished chair.

Second Stuming. When the roll or edge has been sewn in this way the chair is in the state known as first stuffing, and can be covered, if desired, without further stuffing. It is, how ever, an advantage to apply an additional
stuffing, which may be of horsehair, wadding, or other material. It should be sewn in such a way that the stuffing cannot shift or work up into lumps, for which reason ties made with loops of fine twine are provided. The ties are made around the seat about 2 in . from the edge, and several ties provided in the centre portion of the seat. The hair is closely worked under the ties, and when completed with loorsehair the surface should appear to be covered with short, curly pieces. The corners are fitted with buckram or thin cardboard folded and tacked to the cornery of the frame to give it a clearly defined shape
They terminate a little distance below the upper surface of the stiffening, and the edges should be rounded so as not to reveal anv marked angles. This second stuffing may be covered with unbleached calico, or some light material, which is temporarily tacked to the chair, the back corners being nailed and litted in the manner already described.

It only remains to cover the underside of the chair with a lining of canvas, turning under the eclges and tacking them firmly to the underside of the frame, thus covering the web completely. The manner in which this is done is illustrated in Fig. 18.
The chair is now ready for its covering, which may be of any desired material. and is applied as shown in Fig. 19. The cover is carcfully tacked to the sides of the frameworls of the chair and neatly worked around the corners, being finished with any desired kind of gimp. as in Fig. 20.

Stuff-over Work. A more ambitious undertaking is that of completely upholstering a chair from the frame and doing the work on a system usually described as stuff-over. The rough frame can be obtained ready for use or taken from an old chair which has been stripped of its stuffing. Instructions and working drawings for making a frame are given in the article on Easy Chair. The appearance of a divan chair frame is seen in Fig. 2d. Fig. 22 shows the frame after being webbed and sprung.
The first step is to apply the webbing to the underside of the lower framowork of the seat and also to the back part of the framework and the sides. The spaces between the arms are filled in with a picce of scrym or canvas, and the springs are then sewn to the web. A stout cane or similar light, flexible bar is lashed across between the two upper portions of the upright part of the chair frame, attaching it to the springs, as in Fig 22, and not to the framework of the chair.

The purpose of the cane is to provide a resilient edge for the seat. The method of sewing the springs of both back and seat and connecting them together with laid cord is shown in the illustration. In this type of divan chair with a spring edge the lower cross rail on the upper part of the frame, known as the front rail, is located only a few inches above the floor. The cross rail must be sufficiently wide to support the greater portion of the bottom part of the spring. Before the springs at the front are actually fitted, a piece of webbing or a double piece of canvas should be placed between them and the rail, and the end pieces attached to them to avoid any chance of their working forward. Another point is to support the middle portion or waist of the spring by lashing from back to front and from side to side with cord

The seat is covered with spring canvas sewn together around the spring edge so as to case or cnclose it. A still better plan is to cover the springs only, and arrange a separate covering for the spring edge by working the canvas so that the pull on it when the chair is sat upon does not draw the spring edge inwards. This can be managed by temporarily fixing the canvas on the front by passing it over the spring edge, fastening it to the stuffing rails

Upholsterg. Fig. 21. Frame of a divan easy chair ready for covering. Fig. 22. Chair with back and
at the sides of the chair, then removing the temporary tacks from the front part of the canvas and folding it back along the edge of the spring edge. This portion is then fastened 10 the front rail with stout cord or ties, the canvas folded back again over the spring erlge and tacked to the front rail. In this way a furrow is formed between the spring portion and the spring edge, which relieves the latter of the bulk of the pressure from the springs.
The chair is stuffed by the double stufling method. The first stuffing should be with horse hair for preference, tied in the manner already described. After the seat has been stuffed it is covered with scrym: the back and sides are permanently tacked, the scrym being fastened at the front by means of a circular needle and fine twine. The second stuffing is then proceeded with and covered as before The back and arms are started after the seat has been stuffed. The arms may be sprung, if desired, with springs about 4 in. long The spring of the back of the chair should be commenced with the springs. the form being obtained by the use of those of proper length and strength. The swell at the back part should have thicker springs if to 8 in . long. In canvasing the back, care must be taken not to strain the fullness of the materia!, and to obtain neatness by folding where necessary. A few ties are worked through the stuffing at various points to keep the whole firm. The appearance of the work at this stage is scen in Fig. 23

Applying the Cover. In the tina! covering the utmost care will be found necessary in planning the various pieces. and if the material to be used is expensive the amateur will probably tind it well to cut a set of patterns in calico or some cheap material and try them in place to sec that they fit properly. This having been ascertained, the proper material can be cut. It is not necessary to allow much for overlap, as the edges of the material need only be sufficiently long to enable them to be tucked out of sight. Any fastenings that have to be made to the framework are accom. plished with strips of stout calico or linen, known as stretchers, which are sewn on where needed; they serve as an extension of the covering and provide the necessary support.

When all the pieces have been prepared they should be marked for identification purposes. The whole of the seat, back, and other parts should be covered with a sheet of wadding, carefully smoothed down and trimmed at the joints. The various portions of the covering are applied, first the seat, which may be tacked temporarily in place, and then the coverings for the arms and back. Slight adjustment of the covering will ensure the design being central and
any !ines uniform The seat is tacked in position, and after it the arms and the back
In the case of a bordered chair the covering is pinned under and sewn with the circular needle, the border being bulged with wadding and a little hair. The covering is pinned under the edge and corded wherever necessary. Any fullness should be disposed of as the work progresses, by pleating and folding. The outside picecs are then fitted. The bottom of a chair of this type is covered with linen or canvas, as shown in Fig. 24, and the chair is linished with gimp and cord. Gimp is used to outline the design and to cover any bad surface that may show. The cording is secured with a small circular needle and carpet thread. The amateur will probably find it helpful, if a corded edge is to be worked on the tapestry, to apply it first in the manner adopted for making loose covers. Some of the finishing cords and circular gimps are merely applied with tacks or sewn in place, according to the nature of the materials.
Loose Seats and Frames. There are many other applications of upholstery which can be carried out in a similar manner. In some cases loose seats are used and are webbed and upholstered on an independent wood or metal frame. The general procedure is the same as has been described, except that in the case of metal frames the webbing is folded round the rod and secured by sewing When buttons are sewn through the material to form a depression and so add to its appearance and strength, they are secured with fine twine sewn with a long, fine necdle, and they are sewn through the stuffing to the spring canvas. Provision for the button points inust be made in the early stages of stuffing. Jutton work should not be undertaken by the amateur until some experience has been gained in more simple work
Many forms of box-spring mattress are upholstered in substantially the same way as a large spring seat, the underside of the frame being webbed, the springs sewn to them, and the upholstery carried out by the doublestuffing method, with buttons at appropriate intervals. If any difficulty is met with in the actual covering of the chair it can often be met in the finishing stages.
Loose Covers. Detachable coverings made of printed linen, cretonne, chinlz, cotton rep, or gingham are useful cither to protect a delicate upholstery fabric or to cover up a shabby one. An enormous variety of patterns in modern and period designs to suit every conceivable colour scheme arc available in 3 l in width, and many in 50 in When making loose covers for settees, chesterfields and large armchairs, it is sometimes more advantageous to buy the 50 in . width if it saves extensions on either side in order
to get a whole width in the inidd!e to balance the design. Small patterns will join more easily than those with large bunches of llowers or medallions. Plain reps are simplest to plan and cut to advantage, but sonmewhat dull in most rooms unless there is a good deal of colour and decoration elsewhere in the furnishing scheme.

Paper patterns should the laken of the chairs, etc., which require covers. If this is done the total length of material required can be fairly accurately estimated by planning out the patterns and measuring them. Ordinary large newspapers can be used and the type and folds of the sheets are a guide to accurate placing on the chair when taking the pattern. Accuracy in shape and lit is most important, both to appearance and durability.

The parts to be neasured for an armchair or scttee of the usual types are : lnner back; Outer back; Seat, front to back and the width from side to side; Inside arme; Band for front of seat to cover stuffed upholetery or frame; Two outside arins: Two small front arm pieces (not always necessary) ; Frill. Measure off a length twice round the bottom of the chair, if this frill is to be box pleated, $1 \frac{3}{3}$ times round if to be gathered. The depth of the frill varics, but it is usually made just to clear the floor.

A narrow piece may have to be inclucled in the parts to join the inner and outer backs so that they fit nicely at the top. If the arm. chair is straight this extra piece may be avoided by taking the pattern right over and cutting the inner and outer backs in one length. In some chairs with rounded tops, as in Fig. 23, the inner back is taken over the stuffed top, and seamed over the outer edge of the top to the outer back piece.
Take a sheet of paper and pin it to the inner back. Let a fold of the paper run straight down the middle. The pattern need only be cut on one side if the paper is doubled in this way. Cut off by the scams of the upholstery, but an allowance of 6 in. for a tuek in at sides and back of the scat and of 2 in. for turnings must be allowed when cutting out the material. Next take the pattern for the outer back and then for the seat. Pin the paper from the back of the seat with a fold of the doubled paper down the middle. Cut off at sides where it touches the arm and back and at front edge. It should be noted that an allowance for the tuck in of 6 in for both sides and for back of seat portion must be made when cutting material.

Take a pattern of one arm only, lirst from inside over the stuffed edge and cut off at seam. Again ( i in . will have to be allowed for the tuck-in at sides in order to join the seat portion, when cutting material: then pin the paper outside the arm and cut off the pattern by the top seam and lower edge of the chair. Pin a piece of paper to the front of

Fig. 23. Divan easy chair, stuffed and covered with canvas and requiring an outer covering of tapestry or leather or loose cover of cretonne
the arm and cut out to shape of the upholstered piece. Any fullness will have to be pleated up to fit the curve of the front arm. Next take pattern of the straight hand in front of the seat which connects the two arms.

If notches are cut in the pattern pieces at connecting points it is a guide to joining them correctly. A duplicate of the right arin should be cut out in paper to aroid thic danger afterwards of cutting out 2 lefts or 2 rights in the naterial. Mark the patterns of the arms left and right.
When making up, pin the pattern carefully on to the material, remembering to leave 2 in or at least $1 \frac{1}{2} \mathrm{in}$. for turnings and the 6 in . for the tuck-ins where necessary. Make sure that the fabric is quite straight before cut ting out The pieces of material can be pinned on to the chair before sewing to ensure accuracy
The seams may be bound with bias strips of the material or piped For the latter method strips of the material cut on the cross and 1 in. wide are required. Allow an extra $\frac{1}{1}$ yard for each chair, or strips of plain fabric,

Upholstery. Fin. 24. Showing how the bottom of an easy chair is covered with linen or canvas Courtesu of Our Homes and Gardens
such as linen or casement cloth, look well to match the ground colour of a patterned crctonne. Lay the material for the covers right side up to cut out. If a fabric with a large clesign has been chosen see in planning out the pattern pieces on it that the main motifs of the design are well placed to come in the centre of the inner back and seat Also that the design matches on the arms. With a large flowered pattern it is well to allow an extra yard of material as it may cut to waste.

For bound scams (see directions for binding in page 100) the cover shou!d be pinned up with turnings on the right side, and fitted closely on to the chair. For piped scams the turnings are pinned up on the wrong side and the cover should fit easily as the piping takes up room (see page 958). All visible seams should be piped. Any fullness at curves should be neatly darted, gathered or pleated into position.

The tuck-in seams and any others that do not require piping or binding should be machined first. An opening is laft at one side of the outer back, or at both sides if the chair is large or in the casc of a settec, so that the cover can easily be remored and replaced. The edge of the open seam must be faced on onc side and have a wrap over to neaten it on the other. Press studs of strong quality are the most convenient fasteners.

For making the frill join up the pieces and press the seams first. For a hox-pleated frill
take up a 2 -in wide tuck at every 4 in. Flatten ench tuck to make a box pleat (sec Pleating), press, and tack into place along the top. Seam to the cover with neatened raw edge on the inside. A gathered frill is simpler to make. Having joined the piecoss divide them into even sections and gather with double cotton. Divide the cdge of the cover into the same number of sections, pin together, right sides facing, and stitch.

UP JENKINS. This is a parlour ganic suitnble either for children or for adulte, the only apparatus required being a threepenny piece or a sixpenef. The players divide into sides, which occupy different sides of a table. Onc side, usually chosen by toss, has the coin to start with, and all put their hands moder the table, passing the coin from one to the other until it reaches the person destined to hide it. They may do this until the captain of the other side says " Up .Jenkins," when they must hold their clenched hands well above the table for inspection by their opponents. The person who has the coin must do all in his power to kecp it concealed.
Hands may be put on the table in onc or two wnys, according to the opposing captain's choice. "Smash" means that they must bc brought down with open palms as violently as possible ; "crawl " means that they must be put down quietly, and the fingers extended slowly when they are on the table. It is then the business of the opponents to remove all hands from the table except the one containing the coin. If this is cleverly concealed between the thumb and forefinger it is very difficult to detect.

If the captain succeeds in his task, the coin then passes to his side and the ganre proceeds as before. If he does not, but orders off the hand containing the coin, the same side has it again. As the captain's position is one of responsibility, it is best for it to be filled by each member of the side in turn.

URAEMIA. The form of blood poisoning due to the presence in the blood of substances which ought to be excreted in the urine is called uracinia. It may occur quite suddenly, the patient sometimes becoming totally unconscious without previous warning. The condition may arise in any disease of the kidneys and in any other affections in which the urine ceases to be excreted by the kidneys. See Bright's Disease.

URIC ACID. Uric acid describes a nitrogenous substance formed in the body, partly from the wear and tear of the muscles and organs and partly from the oxidation of food. Very small quantities, in the form of sodium urate, are passed out of the hody in the urine. If the urine is very acid, uric acill is deposited in crystals.

Uric acid is increased in a varicty of discased conditions, including gout, leucocythaemia, ague, and pernicious anacmia. But the importance of uric acid as a cause of discase is now considered much less than formerly. It is very slightly soluble in water, but dissolves readily in alkaline solutions. This last quality is of importance in the treatment of gout and gravel.

Some foods give rise to a good deal of the acid, while others are free from the substances out of which it is formed. This fact has led to the diet system which admits the consumption only of what are known as purin-frec foods. The foods which contain in the largest quantitics the bases from which uric acid is made are red meat (beef, mutton, etc.), livers, kidney's, sweetbreads, meat extracts, yolk of egg, peas, beans, and lentils, tea, coffee, and cocoa l'urin-free foods include white bread, tapioca, potatoes, cauliflower, cabbage, lettuce, rice, macaroni, nuts, among regetable foods ; apples, grapes, fige, dates, and raisins, among the fruits; milk, cream, butter, cheesc, fats, white of egg, sugar, honcy

Urn. Silver tea uen, with spirit lamp beneath Courtesu of Chapple \& Mantell

URINE. The purpose of the urine is to remove from the blood certain waste materials formed in the body. Urine is separated from the hlood by the kidneys and passes to the hladder, from which under normal conditions it is discharged in average daily quantities of, roughly, $2 \frac{1}{2}$ pints for an adult. This may, however, vary, being increased in cold weather and diminished in hot weather, when sweating is profuse. The quantity is also greatly affected in some discases, as is the colour.

Various causes produce pain in passing the urine. In simple cases, the enting of more vegetables and fruit may effect a curc ; or a few doses of citrate of potash may be given, 20 gr . in a little water. Stoppage inay be due cither to the kidneys reasing to form urine or to inability to void it from the bladder. The first is called suppression and the second retention. Urgent medical treatment is required in all cases. See Kidncys.

URN. Urns in pottcry, marble, and stone are used for garden ornaments. These are of the classical vase shape with or without lids. The urn used for tea, when large quantitics arc required, is made in silver Sheffield plate, or in copper and various alloys, and old pieces are sought by collectors. Some are fitted with a spirit lamp for heating the tea and kecping it hot. Sometimes the urn is used for boiling water only, and the teapot is filled from it at the table.

The first urns of this kind, which appeared in England about 1740, had lamps placed under them, and the tea was made in them. This clid not produce a very satisfactory tea, so an urn was made which had in its centre a vertical tube into which a round bar of hot iron was dropped, the heating being done in this way.

URNFLOWER. This greenhouse bulb belongs to the amaryllis family. The chief kind is Urceolina pendula, which bears drooping bunches of green and yellow Howers in June. The bulbs should be potted in autumn or in winter in a compost of loam, leaf-mould and sand. Propagation is by offisets which dcvelop on the old bulbs. When the leaves fall watering must be discontinued.

UTRICULARIA. Bladderwort is the common nams of this group, which includes aquatic and insectivorous plants provided with small pitchers by means of which insects arc saught. The chief species is montana, grown in suspended pots and laskets in a hot house in a compost of peat and moss.

UVULA. The small rounded nass of muscle covered with mucous membrane that hangs from the middle of the soft palate is called the uvula. In relaxed sore throat the uvula may elongate till it touches the upper pharynx wall or larynx, when it causes an irritating cough, especially when the patient lies down. This should be remembered when a cough is troublesome at night. Elongation, if it is slight, may be corrected by the doctor painting with glycerin of tannic acid or solution of nitrate of silver. See Pharyngitis.

UVULARIA. These are lily-like herbaceous perennials, related to Solomon's Seal. They are suitable for planting out of doors in moist soil of loam and peat in a partly shaded place, or in the bog garden. The chief kind is

Uoularia. Giracelul stems and drooping yellow owers of the species grandiflors

Uvularia grandiflora, which grows 12-18 in. high and hears ycllow flowers in early summer. Propagation is carried out in spring by separating the underground stems. See Solomon's Scal.

VACCINATION. An inoculation with the liquid contents of a cowpox vesicle is used for the purpose of either preventing an attack of smallpox or of mitigating the effects of small pox which is incubating. It produces a local pock at the site of the injection, but in the large majority of cases no general disease beyond some little feverish disturbance.

Vaccination is usually done on the arm, but in girls the leg may be preferred in order to avoid any disfigurement: In young, restless children it is often extrenely dillicult to prevent rubbing of the skin and irritation, and this difficulty is met with whether the arm is covered or left bare. Wire protectors increase the risk of injury. A piece of boracic lint held in place with a soft bandage or adhesive plaster is the best appliance. The arm must be kept at rest as far as possible.
The best age for vaccination is before teething begins. If smallpox is prevalent the child may be vaccinated even on the first day of life. If vesicles do not appear, as sometimes happens, then the vaccination is not successful, and should be repeated. Protection is said to last for 10 or 12 ycars in the majority of cases, but the period varies in different individuals, and may be as short as two years. It is therefors recom-
mended that a child should be revaccinated between the ages of 7 and 12, and that the operation should be repeated between the ages of 20 and 25 .
If an epidemic of smallpox breaks out, however, it is advisable for everyone likely to be exposed to infection to be vaccinated if his previous vaccination dates back further than five years. When infection with smallpox takes place, if the patient is vaccinated within three days the attack may sometimes be entirely prevented, and if within 8 or 10 days the severity of the attack is usually diminished.

The Law of Vaccination. By the law of England every child must be vaccinated before it is six months old, unless the parent has a conscientious objection to vaccination. It can be performed cither by a private practitioner or by the public vaccinator, who will visit the house and vaccinate the child free of charge. If the parent or person
in charge of the child has an objection to vaccination, he must within four months of the child's birth make a statutory declaration before a commissioner for oaths or a magistrate, and within seven days from that time must send this declaration to the public vaccinator for the district. See Smallpox.

VACCINE. The name vaccine was originally applied to the substance obtained from the vesicles of cowpox. The term is now employed for any substance used for protective inoculation, and what is generally used is an emulsion of dead bacteria, of the kind which produces the disease against which protection is requircd. The use of such vaccines assists the natural action of the body in meeting and combating infection.

The diseases treated by vaccines, either protectivcly or curatively, include influenza, gonorrhoea, acne, pneumonia, tuberculosis enteric fever, common colds, anthrax, rheumatism, and many others.

## Vacuum Cleaners

## The Hygienic Method of Removing Dirt from the Home

In connexion with this article on an important appliance for housebold cleaning the reader is referred to the contributions on Labour Saving; Spring Cleaning; and for safety hints to that on Electricity. See also Oiling

The appliance known as a vacuum cleaner is designed for extracting dirt and dust by suction. The valuc of any particular machine of the type is therefore chielly in its suction powers, which must be strong enough to dislodge and extract deep-lying dirt, as well as to gather up surface dust. The powerful current of air should pass through the thickest carpet and draw out every particle of grit and dust without damaging the fabric.

The fact that the dirt thus extracted is at once drawn into the dust-bag of the machine, instead of being disturbed by swecping with the ordinary broom or brush, when a portion of dust must be allowed to blow about the room to escape even the most careful housewife, makes the vacumn cleamer the most efficient and hygienic cleansing appliance. An additional advantage which is claimed for the best machines is that as the suction created by the vacuum is sufliciently strong to penetrate closely woven materials, a dloor can be cleaned at the same time as the carpet, hangings can be rendered dust-free without taking them down, and dirt can be extracted from upholstered furniture or bedding without removing the covers.

There is a great choice o these cleancrs available. Improvements have rendered most of them capable of removing embedided as well as surface dirt. Also, by means of various accessories, such as special brushes for polished wood floors and linoleum, and others for ledges, different sized nozzles, including a large one for carpets, a smaller one for upholstery and in some models a bookcase nozzle, a complete house cleaning system is devised. There are two main shapes, the handle type such as that illustrated in Fige. 1 and 2, in which the dust-bag hangs on the handle, and the enclosed bag type protected by a light metal case. A variation of the latter type possesses an upright metal container and a patent hinged nozz!e, as is shown in Fig. 3.

Vacuum Cleaner. Fig. 1. Non-electric vacuum cleaner which can be used for cleaning carpets, and also with the various attachmento cor cleaning furniture, walls, beds, and curtains

Vacuum Cleaner. Fig. 2. Electric vacuum cleaner with handle. By simply
detaching the latter, the machine can be used in the hand for cleaning upholstered furniture, stairs and for dusting
British Vacuum Cleaner Engineerino Cor, Itd

With the accessories included in the outfit, the vacuum cleancrs provided with this air purification feature not only clean but to some extent disinfect. The dust-laden air drawn

The enclosed bag type of cleaner is provided with a storage case for the safe retention of the complete apparatus with special clips for each accessory. Unless a separate polisher is used, this type of cleaner is not so suitable where there are large polished floor areas as a handle cleaner with polishing attachment.
When using electric vacuum eleaners it is not desirable to obtain current by means of an adaptor inserted into a pendant lamp-hoider. Plugs and socliets on the skirting board of room or staircase landing are the correct incans of connexion. Note the position of the wall socket for the vacuum cleaner at the foot of the stairs in Fig. 8 of the article on Staircase.
As guarantees arc given with all the best makes of vacuum cleaners, no cleaners of the small pump type which can amateur attempt should be made to repair any e used cither for floors or upliolstry Non leficiency or brealage. Various macine electric vacuum cleaners cost nothing to operate, and, in common with clectric cleancrs, are purchasable on deferred terms. The best makes arc fully guarantecd.
Electric Types. Many of the less expensive electric cleaners of British make are excellent value. The handle type illustrated in Fig. 2 is particularly convenient for gencral cleaning. It may be used at its full length (as seen in the illustration) for carjets nnd floors, or by simply detaching the long handle the machine can be held in the hand for cleaning upholstered furniture, stairs and for gencral dusting. The carpet nozzle is fitted with a patent agitator device which picks up cotton and fluff quickly, as well as extracting embedded dirt. In the upholstery cleaning tool the suction is concentrated, and the nozzle reaches every corner. A lloor brush is also included with the accessories for polishing plain floors. This is titted with a buffer band to avoid damage to furniture or skirtings. The dusting brush for ledges and shelves, etc., has long bristles, and the suction behind them gathers in the disturbed dirt. The same company also makes more expensive models in the enclosed dust-bag type of cleaner.
Cleaners vary much in weight, especially those of the metal-enclosed dust-bag type. Made with a flexible hose and without a handle, such cleaners are very useful for rooms with much furniture and houses with many stairs. The light-weight models are particularly convenient for the latter, as some of the handle machines are large for placing on a step. In the case of much furniture time is saved by the use of such a cleaner as the one illustrated in Fig. 3. It is possible by means of the flexible hose to get under and round the pieces without moving them.
In a house with many delicate ornaments, carved surfaces or radintors a vacuum cleaner which possesees a blowing apparatus is advantageous. The air jet is reversed, and instcad of being sucked in, the dust is blown out of such inaccessible places as the inside of a piano or behind gratings. A damp cloth should be placed to catch the dust as it is disturbed.
Two developments of interest are quietness in operation and a disinfecting pad impreg. nated with a pleasantly scented gerinicide-
deficiency or breakage. Various machines depend for efficiency on proper oiling, and the housewife should thoroughly understand this at time of purchase ; also the correct method for assembling and detaching the various parts and accessorics.
The lubrication of the clectric motor is arranged for by the manufacturers, and the greasc cups require refilling only at long intervals. This job should be attended to by the makers' agent, or the local elcetrical engincer shop.

VACUUM FLASK. Vacuum flasks refer to those which are made with the purposc of maintaining the temperature of liquids put into them, cither hot or cold. This is done by surroundling the containing vessel with an

Fig. 3. In this model the usual type of dust-bar is replaced by a sanitary steel canister. Another fixture which makes for efficiency is the patent hinged nozzle
Tcllus Super Tacuum Cleaner Lid.
outside shell, a space being left between and the air climinated from this space.

Before a vacuum flask is filled with any beverage it should be rinsed with boiling or cold water, according to the temperature of the drink to be carried. This will keep the latter cooler or hotter than it would be if poured directly into the flask. After use, the Hask should be washed out with hot water and left to dry at the side of the stove. If it has held mill, the washing process should be repeated several times to prevent a sour odour from clinging to it. When the flask is not in use the cork should be removed.

Vacuum jars and jugs are purchasable in various shapes and sizes. The jars are made with wide openings to permit casy filling and cleaning, and can be used for kceping soups, stews, or any other food hot, or to maintain ice cream in a proper condition. See Pienic.

VALANCE. The box-pleated or gathered frill which surmounts the curtains of a window or other opening is called a valance. It may be fixed to a pelmet board (see page 927), or to a valance extension supplied with a gliding curtain rail.

Valances round the frame and canopy of a bed are seldom seen except on the 18th century style of bed, an exainple of which is illustrated in page 77. The effect of a valance is now obtained, when desirable, with a pleated frill at cither side of the bedspread.

VALERIAN: The Plant. Most of the valerians are of little value in the garden, but Valeriana l'hu aurea is an exception. It grows 2 ft high, has yellow leaves and white flowers in late summer. It flourishes in ordinary garden soil. The roots of Valeriana officinalis, 3 ft . high, bearing rose pink flowers in summer, are of medicinal value.

Uses of the Drug. Valerian root is a drug with a characteristic, highly disagrecable smell and an unpleasant taste. It is chiefly used in medicinc in the treatment of hysteria and similar nervous conditions, sometimes with striking effect.

VALLAURIS WARE. Two types of French pottery are associated with the village of Vallauris, near Cannes. One of these consists of kitchen utensils, including a porous terra cotta, often covered with an opaque green glaze, with or without Horal decorations.
A more important class of decorated faience comprises the majolica and lustred ware developed especially by the Massier family. Discarding the conventional shapes introduced from China, the Vallauris potter, Clement Massier, based his patterns upon the Greek vases, and decorated them in brilliant colours resembling old oriental lustre and medieval majolica.
The ware, usually a leadglazed soft-paste, comprises ornaments covered with lustrous fish-scales, peacock feathers, etc., or with silvered lustre enriched with colour glazes.

VALLOTA. This is an alternntive name for the halfhardy greenhouse or room win. dow evergreen Howering bulb known as the Scarborough lily. See Scarborough Lily.
VALSE. This is the French name for the dance more usually spoken of as a waltz. It is used considerably in music for works which are written in waltz time, such ns Chopin's waltzes. Sce Dancing; Waltz.

## Valves for Wireless Receivers

## The Different Kinds, Their Characteristics and Uses

This contribution deals in a thorough yct concise manner with the types of thermionic valve in use. After a brief account of the basic principles upon which valves work, information is given about the various types and their function in a modern receiving set. Finally the reader is told howto select valves for given purposes, and how to read the characteristic curves which are issued by Rectifier: Wireless Reception

The thermionic valve is a vacuum tube grid bias. The grid bias plug shou!d not at containing two or more electrodes, and may any time he withdrawn from the grid battery be cinployed for either rectification or ampli. fication. The electrodes are enclosed in a glass bulb, the connecting wires from which are taken through the " pinch" to pins in a moulded base usually of bakelite. The valve is inserted in a valve-holder provided with terminals so that connexion can be made to suitable points in the circuit.

A threc-electrode valve or triode comprises the anode. grid and enthode In the battery operated type the cathode also forms the filament, whereas in the indirectly heated mains type the cathode and filament (heater) are separate. The cathode, upon being heated, emits electrons, and if the anode is caused to become positive with respect to the cathode, a current passes through the valve from cathode to anode

The potential of the grid, relative to the cathode, controls the electron stream. A positive potential applied to the grid will cause a considerable current (anole current) to flow through the valve. Conversely the application of a negative potential to the grid (negative grid bias) will decrease the anode current, and if this negative potential is made sufficiently great no electrons will reach the anode, and consequently no current whatever will pass from the cathode to the anode.

A curve showing the anode current at a given high tension voltage for different values of grid potential is called a static characteristic. In practice under working conditions this curve undergoes a change and is then referred to as the dynamic characteristie.

In order that a valve miay function as a distortionless low-frequency magnifier, it is necessary to operate it at a suitable point along thic characteristic, and the correct values of negative grid bias for various high tension voltages are given by the valve makers on the leaflet supplied with the valve. These should be adhered to.
The valve may lose its emission by applicntion of too little negative grid bias or a positive

Valve. Fig. 1 Electrode assembly of three typical medern valves. A. Marconi and Osran valve for high-frequency amplifcation. C. Mullard special power grid detector Courtesn of The wircless World.
while high tension is being applied to the anode. Moreover the filmnent nust not be overrun.

In addition to the threc electrode valve, there are certain other valves which are used for special purposes. For instancc, the screen grid (tetrode) valve possesses an extra grid, known as the screening grid, and is cominonly employed as a high-frequency ainplifier. The pentode has three gridy and provides a high degree of amplification when used as low frequenoy magnifier. The bi-grid valve is a form of four electrode valve which can be employed as a detector-oscillator in a super-betcrodyne.

The Different Types. It is convenient when considering the question of valves to deal with them in the order in which they appear in the modern wireless receiver, namely, highfrequency amplifier, detector and output valve, but before doing this it is as well to make clear at the outset the essential difference between a valve intended for use with batteries only, and one intended for use with ordinary household lighting mains.

A valve intended for use in an "all-mains" receiver is-except in the case of certain types of output valve-provided with an independent cathode for the emission of electrons, this being heated by a filament in close proximity to but not in electrical contact with it. This arrangement is necessary in order to prevent hum due to fluctuations of the filament temperature. Apart from this, the indirectly heated cathode confers severa other advantages in the valve, all of which conduce to greater efficiency than is the case where the filament itself is used for electron emission, as it is in the battery-driven type of valve.

Owing to temperature losses between the heater and the cathode of the indirectly heated type of valve it is necessary that a filament wattage be used, which it is far too uneconomical to obtain from batteries of any kind, but which is exceedingly low when compared with the consumption of an ordinary household lamp.

The modern screen-grid valre, which was first introduced in 1997, has long since completely displaced the old neutralised triode By its use it is possible to bring abont complete stability in an H.F. amplifier, employing quite straightfor. ward screcining arrangements. It gives a far higher degree of magnification than the triode, and since it does not depend on large di-ametersuper-efficient coils for this, it is possible for compactness to be achieved with an actual gain in amplitication. Against these ad-
vantages must be set the fact that the valve is definitely less selective than the neutralised triode. This is due to the fact that its characteristics do not enable it to accept such a large input grid voltage swing, and therefore the valve overloads easily ; the result is that it rectifies, and not only selectivity but also quality is marred. In addition to this, rectification taking place in the $H . F$ valve or valves in the case of a mainsdriven set causes an increased tendency toward hum and kindred troubles, in spite of the precautions that may be taken elsewhere in the set to prevent these evils arising.
These difficulties have been overcome to a very large extent by improvements in valve characteristics, but chiefly by the development of the "band-pass filter" system of tuning, which may be briefly described as a system of double-circuit tuning-usually preceding the first valve in a receiver-whereby a considerablc degree of selectivity is obtained without the attenuation of the upper musical frequencies usually associated with the ordinary sharply.tuned single circuit arrangement.
The Variable-Mu S.G. Valve. Although results which are exceedingly good from all points of view can be obtained from a straight. forward receiver with a modern system of tuning, there is still much room for improvement, and a very big step forward has been made comparatively recently by the intro duction of a highly specialised form of screengrid valve known as the "varinble-mu." This new valve, owing to its relatively heavy high tension current demands and to various other reasons, is only available as an indirectlyheated mains valve. It has less sensitivity than the ordinary screcn-grid valve, but since power consumption offers no difficulty in the case of the mains user, this deficiency can be casily remedied by the use of an extra stage of H.F. amplification. The great advantage of the variable mu valve is that it can handle a large input without overloading, and from this statement alonc it will be seen that all the disadvantages already mentioned as appertaining to the ordinary S.G. valves are disposed of. Another type of H.F. valve having similar good points is the special highfrequency pentode valve which has rccently made its appearance

Rectifiers. It is well known that the ordinary leaky grid detector held the field for a very long time, owing to its simplicity and sensitivity. Indeed, it still shares the honours with the anode-bend detector in the case of battery-driven reccivers, where the utmost economy in the matter of H.T'. current consumption is necessary. The anode-bend arrangement is capable of better quality than the leaky-grid detector except on weak or rery deeply modulated signals, and owing to the absence of grid current, better selectivity is obtained with it; however, its sensitivity is less than that of the leaky-grid detector, and smoothness of reaction control is rather difficult to achieve. At one time a valve of high A.C. resistance was always used as the anode bend rectifier, as it was alnost invariably followed by resistance-capacity coupling. Nowadays, however, it is better to use a valve of moderately low A.C. resistanceusually designated by valve makers by the prefix L-and to follow it by a transformer of high primary impedance.

The mains user has an advantage over the battery user because he can afford the necesaary high plate voltage and heavy plate current associated with the power grid rectitier, which is probably the most satisfactory de tector for all-round use, insomuch that it is undoubtedly the arrangement which gives the nearest approach to distortionless results using one valve only. It has the disadvantage that it tends to cause considerable loss of selectivity; but this is, however, discounted

Valve. Fig. 2. Mazda indirectly heated power pentode for mains. Fig. 3. Electrode assembly of Mazda pentode for tattery operation
consideration the design of set with which the valves are to " be used, but nevertheless a few gencral rules can be given. Ignoring the casc of receivers specially designed for variable-mu valves, al! rcceivers will naturally usc an S.G. valve in the H.F. stage. If the tuning arrangements of the set are not of the modern band pass type, it is well to aim at a valve with a relatively large grid owing acceptance in order to avoid the evils attendant on over-loading which have already been cliscussed. If, however, a preselection band pass filter is used, a valve capable of giving greater amplification with its inevitably lower grid swing acceptance should be chosen This consideration more particularly applies to sets having one H.F. stage only, where a! amplification has to be done by the one valve, and it is equally applicable both to battery and to mains driven receivers.

In the case of the detector,
to a large extent by the use of proper tuning circuits preceding it.
Various special arrangements employing more than one valve for detection such, for example, as push-pull detection, have heen brought forward to minimize distortion, but these have not proved altogether popular owing to the fact that they add to the complications and initial cost of the receiver, and at present they are usually to be found only in receivers designed regardless of expense or of the total number of valves used. The screen-grid and pentode type of valve have already been employed by scveral designers in the detector position, and it is very probable that in the future the multi-electrode valve will figure a great deal more in this pait of the set than is the case at present

Output Valves. With regard to the output valve, one can employ either a triode or a power pentode. At one time the sole advan. tage of the pentode valve lay in the fact that it gave extra amplification and enabled a somewhat grenter signal strength to be obtained than was the case with a triode, but in other respects it was to bc avoided, owing to varions disadvantages, the most important of which was its tendency to overemphasize the upper musical frequencies, due chieHy to the fact that it was mistakenly used with output circuit arrangements suited only to a triode. The modern power pentode valve has shed all its earlier disadvantages, however, now that so much more is known of its correct operating conditions, and provided that proper precautions are taken in the design of the output circuit, the quality obtainable from it is fully as good as that obtainable from a triode.

In the case of battery driven receivers, tlie early types of pentode were not of very much use, because of their extravagance in the matter of plate current and because in the twovolt range, at any rate, they had no greater power output than a triode The modern low consumption type of pentode, however, is the ideal output valve for the hattery man, both from the economy and the quality points of view, and, furthermore, it enables him definitely to dispense with a stage of amplification between the detector and output valves, thus greatly lessening the tendency of the L.F. part of the receiver to approach the oscillation point.
Choice of Valves. When choosing valves of any type it is necessary to take into
valve of medium A.C. resistance-classified by valve manufacturers under the heading of H.L. -will nsually be found suitable for power grid detection in a mains-driven receiver, and indeed a similar type of valve will serve for all types of detector, irrespective of whether the receiver is operated from the mains or from batteries.

The choice of an output valve is the most important of all, for it is the devicc which actually operates the loud speaker. In the first place, it must give the full jower ontput demanded by the loud speaker with which it is to be used. This will vary widely but will never be inuch helow 400 milliwatts. A useful, average value is 1,000 milliwatts, although the battery user will usually have to content himself with half this in the interests of cconomy in running costs. Whether the valve should be of the pentode or triode type depends upon the design of the receiver, but whichever type is used, care should be taken to sec that the transformer which will couple it to the loud speaker is of the correct ratio.

Valve Curves. An article on valves would not be complete without reference to the characteristic curves which nowadays are lublished by all valve manufacturers. Although valve cha. racteristics may be had in tabulated form, a curve is far more useful and helpful. It enables the principal valve characteristics to be seen at a glance in a manner which no amount of attention to tabulated data could do; indeed, if it be compared to a picture and the tabulated data to a written description of the place which the picture portrays, some idea of its inıportance will be obtained.

The most common curve is the one which shows the relationshij) between grid voltage and anode current at
various lixed values of plate voltage, but it must be admitted that the utility of this type of curve is very restricted, and if employed for determining the maximum grid voltare swing of a valve or for determining the value of grid bias, very misleading results can be produced, and for this purpose the type of curve showing the relationship between anode-volts and anode-current for equal increments of grid bias should be employed. In addition, this latter type of curve (which is, without doubt, the most useful of all when dealing with any type of valve, be it S.G., detector or output), enables the "load line" of the valve to be obtained, and by using this as the hypotenuse of a right-angled triangle, the actual value of the "optimum load " expressed in ohms, and of the maximum undistorted power output expressed in milliwatts can be calculated very simply. The first named characteristic is vitally necessary in order to cuable a loud speaker of the correct impedance to be chosen or, alternatively, to permit of the correct calculation of the ratio of the transformer which it will be necessary to use between the output valve and an cxisting loud speaker.

In the case of a screen-grid va!ve, the anode-volt anode-current curves are again cxtremely valuable for determining the load line which, in this case, it is necessary to ascertain in order to prevent encroaching upon what is known as the " nogative resistance kink," which would have the effect of causing loss of selectivity and also hopeless instability. Curves of this trpe are no less useful in assisting in the choice of a detector valve, since such things as rectification efficiency and the percentage harmonic distortion with varying depths of modulation can be easily determined

When choosing a ha!f-wave or full-wave rectifying valve for use in an A.C. mains receiver or battery climinator, it is important to study carefully the voltage regulation curve (which reveals the value of D.C. volts available with varying degrees of load) in order to obtain one which is suited to the particular set in question. On the other hand, if design. ing a receiver, this curve must be studied in order to choose or design a suitable power transformer for the valve and also in order that the designer may be in a position to calculate correctly the value of the various voltage dropping resistances which must be used in the receiver. Similar curves are available in the case of metal rectifiers, which few people seem to realize are valies just as much as their thermionic counterparts.

## Valves in Motor Vehicles

## Practical Information About the Different Types

This is one of a group of articles in our work which deals with various parts of the motor car. The reader is therefore referred to such headings as Exhaust; Four-stroke; Internal Combustion Engine ; Motor Car. See also Pump

The flow of a liquid or gas through a port or levers, mounted side by side on a fixed opening is always controlled by a valve, of shaft, each being operated from a separatc which many types are in use. To the motorist cam. The camshaft is some way above the the inlet and exhaust valves, which control crankshaft, from which it has to be driven the working of the engine cylinders, are at half speed, various methods of driving probably the most important and certainly call for most care and attention. Other valves, though essential, so seldom even require inspection that their presence is apt to be overlooked. Among these may be mentioned tire valves, the carburetter throttle valve and needle valve, the valves in the Autovac or in the fuel pump, and ball and similar one-way or non-return valves used in the engine lubrication system, in tire pumps, in grease nipples, and in the grease gun. Only engine valves and tire valves will here be considered in detail.

When the internal combustion engine was first applied to the propulsion of vehicles, expcriments were made with valves of various types, but only the sleeve valve and the ordinary lift valve now survive
The usual conical lift valves, known also as mushroom or poppet valves, con sist of a head with a narrow conical face and a stem working in against a flange on the a guide. The head and the stem merge into one another with a good radius to facilitate the flow of the gases and to avoid the possibility of the stem breaking off under the head.

The several ways in which the valves may be arranged in relation to the enginc cylinder are shown diagrammatically in Fig. l. The side valve engine shown at $\dot{B}$ is to-day used as widely as the overhead valve type shown at C and D. In the former, the combustion chamber extends from the cylinder over the exhaust and inlet valves which arc arranged side by side (one only bcing shown), and both being operated from separatc cams on the samecanshaft. The overhead valve engine gives a more compact com. bustionchamber, the valves being inverted so that they open down wards. Two methods are adopted forvalve operation. In one method, shown at $C$. the exhaust and inlet valves are buth opened being adopted, such as a vertical shaft with skew or bevel gearing on the upper and lower ends, or chain gearing with or without toothed gearing. In the push rod construction shown at D only one valve is visible, the other being arranged in line with it.
A detailed section of the popular side valve engine is shown in Fig. 2, the combustion chamber being shown as formed in the detachable head. The stem of the valve works in a bush, e, pressed into the main casting. A coiled or helical valve spring $f$ abuts at its upper end ower end engages a washer $a$ of $e$, while its which is secured to the lower end of the valve stem by a cotter. The valve is raised from its seat, when required, by the cam $b$. The can engages the lower end of the sliding tappet $c$. the upper end of which lifts the valve. In some constructions the lower end of the tappet carries a roller which runs on the camshaft, but more frequently it is provided with a disk shaped end, as shown. The tappet is free to rotate so that wear is distributed all over the face of the disk. A stem $d$ may be screwed into and out of the upper end of the tappet in order to vary the clearance between the head of this screw and the lower end of the valve stem.
by casting in which the springs by rocking and the upper ends of the

The screw, after it has been adjusted, is secured in position by a locknut. A small but definite clearance must always bc left to ensure that the valve can engage its seat properly, except when it is lifted by the cam The tappet should always be set to give the clearance specified by the makers. In side valve engines this is usually of the order of 004 in., when the engina is cold. Greater clearance will create noiss and may, if excessive, cause wear and affect the running of the engine A smaller clearance will prob. ably, when the engine is hot, result in the valve not seating properly, and in that case there will be some loss of power, while the valve face and the valve seat will certainly be damaged by the leakage past them of the flaming gases.

The recesses in the cylinder

Fig. 3. Overhead valve engine with push-rod operation. Fig. 1. Three types of valve lifters that may be set and left unattended. Fig. 5. Double sleeve valve Daimler engine ; in which inlet and exhaust porta are opened and closed by sleeves
valve engines The push rods pass with
complete freedom through openings in the complete freedom through openings in the
detachable head. The rocking levers are in nearly all cases lubricated automatically and the uperating gear is protected by a cover, but it is well with many engines occasionally to remove the cover and use the oil can to ensure that some oil reaches all the working parts such as valve stems and the ends of rocking levers.

Whenever an engine is decarbonized it is desirable that the valves should be ground in until all marks are renoved If this operation is neglected there is considerable risk that the pitting marks will penetrate somewhat deeply and that a considerable amount -of metal will have to be removed at a later stage when truing up the valves. In order to detach the valve it is necessury first to compress the valve spring and collar or washer so that the cotter pin or similar securing device may be removed from the stem, after which the valve may be removed The spring is in nearly all cases too stiff to be compressed by the fingers, and a proper valve lifter or valve spring compressor saves a great deal of time Many difierent designs of valve lifter are available for this purpose ; examples being shown in Fig. 4. The valve should be down on its seat before the valve lifter is brought into use, and the forked end of the lever should be placed squarely in position under the spring collar to avoid the valve rising with the spring when it is compressed. The collar when lifted clear allows the cotter pin to be readily removed. The valve and lifter may then be taken out together or the spring may be released, but this should always be done gradually.

## Sleeve Valve Engines

The sudden and jerky operation of the ordinary lift valve has stimulated attempts to replace it by valves having a more continuous movement, but practically the only successful alternative is the sleeve valve.

A section through a Daimler double-sleeve engine is shown in Fig. 5. In this construction the piston moves up and down within a thin steel sleeve or tube $a$, which is also given a short vertical travel by a rod connected to a small crank on a shaft driven at half-engine speed. Between the inner sleeve $a$ and the main cylinder casting is interposed an additional sleeve $c$ which is similarly reciprocated by a connecting rod $b$, from the half-time shaft. The up and down movements of the two slecves are out of phase, but they co-operate to ensure quick opening and closing of the ports connecting the cylinder to the inlet and the exhaust passages
Sleeve vaive engines are very silent in operation and valve grinding, and valve adjustments are quite unnecessary. The rate of oil consumption is, however, somewhat higher than in poppet valve engines, this being indicated, particularly when starting, by blue smoke from the exhaust.

In single sleeve valve engines the sleeve is interposed between the piston and the cylinder casting. It receives an elliptical movement, being operated at half-engine speed from a crank in such a way that it is moved both up and down and is given a small a mount of rotation.
Tire Valves. Valves used for tire inflation are always of the non-return type, and since there must be no air leakage, although the pressure may be considerable, a rubber seal or seat is always used. In the ordinary cycle type construction shown in Fig. 6 the stem which projects inwards is covered hy a short length of thin rubber tube. When the valve cap is removed air may be forced upwards through the centre of the stem and then sideways through a small hole which opens against the inside of the rubber tube. The tube is thereby lifted and air flowa into the tire but
the tube prevents any return of air through the stem
On motor car and motor cycle tires the Schrader valve shown in Fig. 7 is gencrally employed. The valve and its seat are shown separate!y at A and form a complete unit. which may be screwed into the stem $b$ when the cap $c$ is removed, by means of 'a slot $d$, in the head of the cap The two main parts of the valve unit include: (l) a screw $e$, and a conical rubber plug $f$, which engages a

Valve. Fig. 日. Showing construction of a cycle type valve. Fig. 7. Schrader tire valve; valve unit. shown separately at $A$, is readily removable
stem; and (2) a metal ring $y$, enclosing a rubiber valve $h$, which bears on the metal seat $j$. The parts $g$ and $h$ are secured to a wire stem running from end to end with some clearance whore it passes through the part $e, f, g$ The valve $h$ is forced on to its seat $j$, by the pressure in the tire, but is lifted off during inflation by air forced through the space between the stem $k$, the screw $e$, and plug f. These valves are practically impossible to repair, and on the rare occasions when trouble develops new ones should be fitted.

VANILLA: The Plant. The vanilla is a hothouse climbing orchid, which may be grown in pots in the hothouse and trained up the rafters. The flowers are borne in summer, and are followed by seed pods which are from 4 in . to 6 in . in length. Water freely during the hot months but only occasionally Juring the colll weather.
The vanilla plant grows best in a mixture of peat and sphagnun1 moss, and the pots or pans should be wcll drained with clean crocks. See Orchid.

VANILLA: The Flavouring. The dried porls of the vanilla plant, which are used in cookery and confectionery as a llavouring, are about 7 in . long and dark brown in colour, the best qualities being nearly hlack. A small piece of the dried pod, or bean, as it is often called, if broken off and adiled to milk or cream imparts a delicate aromatic llavour.
The extract is commonly used for household purposes, but, although more convenient, it does not possess the same qualities for flavouring that belong to the bean itself. The housewife should carefully avoid all cheap extracts of vanilla, as they have not the true vanilla flavour. Vanilla is a favourite flavouring for ices, custards, blancmange, caramels and other sweets, biscuits, and small fancy cakes.
Vanilla Sauce. To $\frac{1}{2} \mathrm{pt}$. white foundation sauce add 2 teaspoonfuls castor sugar. After cooking the sauce, as described in the article under that heading, add vanilla essence to taste, and serve in a hot tureen.
Vanilla Shape. An inexpensive and quickly prepared sweet, this is made in the follow-
ing way: Heat up 1 pt. milk, dissolve in it $\frac{1}{2} \mathrm{oz}$. sheet gelatinc, and then add the beaten yolks of two eggs and sugar and vanilla flavouring to taste. The milk must not be boiling. otherwise the eggs will curdle. Lastly, beat in the stiflly whipped white of cgg and the strained juice of a lemon pour the whole into a fancy mould previously rinsed with cold water, and leave it to set. When firm, turn it out and serve it with thick cold custard or whipped cream.

Vanilla Wafer. Sicve $\frac{1}{2}$ lb. Hour and $\frac{1}{2}$ teaspoonful salt into a basin and make a well in the centre. Beat up the yolks of 2 eggs, add to them I teaspoonfu! cold water, and then pour them into the centre of the flour, working in as much of the latter as the eggs will take up. Then add gradually enough water to mix the whole to a stiff dough, turn the latter on to a floured board, and knead it for about 10 min . or until the dough is smooth and soft.

Roll it out very thinly, stamp it into rounds or fancy shapes, and bake thesc in a hot oven on a slightly floured baking-tin for 5 to 8 min . or until they are yellowish-brown in coloup. When they are donc, brush them over with the whipped white of egg, dip them in powdered icing sugar, and put them back into the oven for 2 or 3 min ., when they will be ready to serve.

VANISHING CREAM. Unlike cold? cream and other similar toilet preparations, vanishing cream is non-greasy, and is used by many women as a basis for face powder.

VAPORIZER. The appliance known as a vaporizer is used for converting a combustible liquid into a gaseous state. In its domestic applications the vaporizer is limited chiefly to apparatus for generating light or heat The usual plan is to force a sma!! quantity of the liquid through a restricted space as, for example, a fine bore tube, or block of metal with small-sized holes through it, which has been heated to a sufficiently high temperature to convert the liquid into gas.

Another plan is to force the liquid through a spiral tube on to a revolving vane, which, by distributing it over a large area, breaks it up into fine particles, forming a gaseous mixture when air is added. By a third methodi the liquid is allowed to How by gravity into a chamber, the lower portion of which is filled with absorbent material, such as asbestos wick or some special form of porous brick. This becomes moistened with the liquid, which on exposure to the air is given off as vapour.
The name vaporizer is also given to an arrangement of various kinds for producing a fine spray of some liquid. See Air Gas, Blow Lamp; Cooker; Lamp: Oil Sprayer.

VAPOUR BATH. In chills, oncoming colds, rheumatism, certain diseases of the kidneys, and other conditions for which it is desirable to produce frec perspiration vapour baths may be used for the purpose. Some skin diseases, such as psoriasis, and types of eczema may also be benefited by a course of these baths. As they are however, very depressing in their effect, no person who has a weak heart should take them without. medical advice.
A simple arrangement for taking a hot vapour bath at home is to sit on a wooden chair placed over a large pan containing a few inches of hot water. Blankets should then be draped over the body, chair, and pan in the form of a tent, the body acting as the tent pole. Someone should then lift up one corner of the blanket, and place in the hot water (by the aid of some firc-tongs) a brick which has been heated in the fire. As the steam from the first brick subsides another may be added, until, after about 10 min ., a profuse perspiration breaks out. This may be followed by a cold plunge. See Turkish Bath.

VAPOURER MOTH. The caterpillars of this moth attack the foliage of a great variety of plants, including most of the fruit trees, and a large variety of other trees. They also devour herhaceous plants in garden and greenhouse. and may be described as general fceders.

The following method of dealing with this pest is in Leaflet 161 issued by the Ministry

Vapourer Moth. the caterpillars of which attack both greenhouse and garden plants
ous may be dealt with by hand conspicu spraying is notdesirable, or shaken off their food plant and destroyed from May to September

Attacked plants may be sprayed with lead arsenate to poison the foliage on which the caterpillars are feeding. The formula is $\frac{1}{2} \mathrm{lb}$. of lead arsenate paste dissolved in 10 to 12 gallons of water. The females being wingless and moving very little, the species can only apread in the catcrpillar stage. See Fruit: Insecticide: Pear; Spraying

VARICOSE VEIN. Firom a variety of causes veins often become dilated and tortuous, when they are said to be varicose. The most common site is in the legs. Policemen, shop assistants, washerwomen, and others whose work involves standing for most of the day are the principal victims. Tight garters and constipation, where frequent and prolonged, may have the same result. Thrombosis. that is. the formation of a blond-clot which results from inflammation of the vein. may sometimes block the vessel and cause dilatation of the veins below. Pregnancy and pelvis tumours are other causes. Once the awelling begins it tends to increase. Ulcers may develop and be very difficult to heal.

Garters should never be worn in any circumstances. Constipation should be prevented. Long standing must be avoided, and in the evening or at intervals during the day it is well to sit or lie on a couch and raise the legs. Exercise is necessary, but should be moderate. Cycling is one of the best forms, and some people find improvement follows dancing if not carried to excess.

So long as the veins do not give trouble or increase much in size nothing more may be necessary. Very often, however, some support is needed. If an elastic stocking is worn it should be of a good quality and a pcrfect fit. When bandages are used, the patient must learn to apply them properly. Any support, whether stocking or bandage, should he put on before getting out of bed and only removed at night while lying down in bed.

When the veins become painful, when ulceration or eczema is likely to ensue, or when the veins adhere to the skin and the risk of rupture arises, a radical cure should be sought. This may be procured by operation, but most people prefer to have their veins treated with injections of sodium salicylate or some other substance that produces a firm clot and thus closes it. See Elastic Stocking; Thrombosis; Ulcer.

VARIEGATION : In Plants. There are many variegated or coloured-leaved varietien of various shrubs and plants which normally have green leaves. The leaf colouring is usually white and green, ycllow and green, or cream and green, though there is a purplish tinge in some. Familiar examples are the variegated aspidistra, euonymus, privet, india-rubber plant and tradescantia. The leaves are liable to lose their colouring if the plante are grown in rich soil. See India-rubber Plant.

## Varnish and Varnishing

## How the Amateur Can Obtain the Best Results

In this contribution, after an account of the kinds of varnish suitable for home use, the process
of varnishing is described. Allied information will be found in the entries on the woods,
fixtures and pieces of furniture that are varnished, e.g. Door: Floor; Oak: Table. See also Brush: Enamel; Paint; Sprayer; Stain

Varnish is a transparent liquid used to form or linseed oil, and on no account should a protective coating with a glossy finish on woodwork and other material. It is applied with a brush or sometimes a spray, and after the lapse of a period varying in length according to the nature of the ingredients the varnish dries, leaving a hard and glass-like skin on the surface.

Generally speaking, varnishes are composed of oil, alcohol or water into which are dissolved various gums, resins, or colouring substances. Oil varnishes are the best for most house decoration. Spirit varnishes are employed for floors and margins, and are quicker in drying. Both kinds may be obtained ready made, and the best quality should always be used Cheap varnishes are composed of poor ingredients, which not only render then difficult of application and cause an uneven and streaky finish, but make the work liable to such blemishes as bloom and a tendency to remain wet.
Varnishes for household use comprise inside and outside. The latter variety is more suited to withstand the effects of the atmosphere, and it may also be used for interior work. Inside varniah should never be used for work out of doors, as it is not only inferior in waterproof qualities, but is apt to peel off when exposed to sunlight. A better class of varnish for outside work where a very good quality of tinish is necessary is that known as carriage varnish. These varietios are all made in various shades, white, light or dark oak, pale and dark, the two latter referring to carriage varnish. It is not advisable to apply two consecutive coats of varnishes made by different makers or of a different nature, as in the process of drying one may contract more than the other and so cause the surface to crack and exhibit other blemishes.

To a pply varnish successfully requires some experience. This can be obtained by experimenting, and it is advisable for the amateur, before com. mencing any serious work, to practise on spare pieces of wood. A suitable class of varnish should be selected in accordance with the nature of the work and the position in which it will be exposed

The Necessary Materials. The materials required are, firstly, two good camel or hog's hair brushes, one of these being wide and flat for wide surfaces, and the other rather smaller, for working in corners, etc. The brushes should be kept with the hair in either varnish
 Varnisting a Door. Fig. 1. Working the first coat on the panels with a flat brush. Fig. 2. Using the felting pad between the two coats of vareish. The motion of the band should be circular
the varnish be allowed to harden on the bristles. A jar can be used specially for the purpose of storing them, partially filled with oil or varnish. The cork should be a good fit, and have two holes cut through the centre large enough for the brush handles to pass through and tight enough to prevent them dropping right through into the jar. If necessary, a nail may be put loosely through the handle in order to hold the brush. The bristles only should be submerged, and it is a bad practice in all phases of the work to allow the handles to become covered with the varnish. If oil is used to keep the brushes in they should be thoroughly cleansed of the oil before use.

Two other requirements are glass paper and a felting pad, these being used for rubbing the work down between the costs. The pad consists simply of a piece of felt, and if desired may be mounted on a wooden base; the method of using it is described later. Pumice powder, for use in conjunction with the felting pad, is also needed. Apart from the bottle or can in which the varnish is stored, an open vessel is required in which to pour the varnish during the actual operation.

For indoor work the chief thing to guard against is a draught. The temperature should be moderate and consistent, and in cases where an open door or window causing a draught is unavoidable a gond plan is to use a screen. Another danger to be avoided is dust, which once it clings to wet varnish cannot be removed. In many cases it is necessary to rub the work down with glass paper before varnishing, and it is easential that the dust caused thereby be allowed to settle and be removed from the work before commencing to varnish.

The Processes Described. When new wond is to be varnished it is first necessary to prepare the surface with size, to prevent the wood from soaking up the varnish and thereby causing it to become blotchy and uneven. If the wond is not stained it should be first glass papered flat and smooth. Size should then be applied with a brush. If the wond is of a coarse, open nature the size should be rather thicker, and when the whole surface has been coated it should be allowed to dry thoroughly Care must be taken to prevent the size running into quirks and corners and accumulating, these parts being brushed out with a fairly dry brush.

A small quantity of varnish is poured into the open vessel, just sufficient for the immediate portion of the work to be covered. It is inadvisable to pour out too much, as it is liable to thicken, owing to evaporation.

Varnishing a Door. To get the best results a job like the varnishing of an outer door should be done at a time when there is the least likelihood of dust or disturbance. Probably the early morning would be chosen for the work. After removing any dust and rubbing down any parts which require
such treatment, the application of the varnish may be commenced.

The brush is dipped into the varnish, to about one-thind the length of the brist!es and applied straight to the door. A surplus should be avoided so that the brush does not drip It is worked in the same direction as the grain of the wood with a light pressure, then crosswise once, and linally with single strolies with the grain. It is necessary to work smartly, as the varnish scts fairly quickly The object in view is to obtain a flat surface free from brush marks. Lxperience will soon show the worker just how much the varnish may be worked

As shown in Fig. 1, the panclled portions of the door are varnished lirst, taking care to work well into the corners and edges. The varnish should be applied in a fair body, but great care must be exercised to avoid rumning. Having completed the recessed part, the rails and stiles are next attended to The stiles are first varnished, and the rails last, so that the joints are cleanly linished off. If, on a similar cloor, monldings are present, these should be picked in lastly with the smaller brush, being careful to avoid touching the panels or stiles, and working the varnish well out of the corners. The whole should then be left to dry thoroughly.
The sane process is adopted when varnishing all kinds of panelled work, working the panels first, then the rails, stiles, and finishing with the mouldings. All the joints in the woodwork should be cleanly finished, so that the brush is always drawn in the same direction as the grain of the wood. The time for drying varies, according to the varnish used and the atmospheric conditions, and this can only be decided by the conditions under which the amateur is working

Rubbing Down. When thoroughly ciry the wiole should be rubhed down with the felting pad. This is done by damping the work slightly with a sponge, dipping the felting pad into the pumicc powder, and rubling it on the surface with a circular motion, as in Fig. シ. The guirks and mouldings may be smoothed down with fine glass paper, care being taken not to rub the projections too vigorously, as this may remove the varnish, and when the second coat is applied it will present a patchy appearance owing to the varnisl। sinking into the bare wond. The whole slould be dried with a duster, removing any traces of dust caused by the glass paper.
The sccond coat is applied in a similar way to the first. If only two coats are desired, this should be finished off as cleanly as possible, the tinal strokes being always in onc direction and the bruah only lightly charged. When a third coat is to be applied, this is done in a similar way, rubbing down between each and being sure that the first coat is quite diy liefore attempting further work. Working on ret or tacky varnish has the effect of pulling off the previous coat. Thic process alove detailed may be arlopted for all ontside work.
Re-varnishing woodwork requires a similar process, but it must be rememhered that rarnish is transparent, and any defects in the under coat will slow plainly when the whole is tinished, so that if the original varnish is hadly damaged it will probably le best entirely to remove it. If, however, it is in fair condition, it should be first thoroughly cleaned with soap and water to remove any dirt and grease. A cotton rag is used for this purpose.
A painted surface may be varnished over. provider that the surface is Hat and not glossy. Plenty of turpentine in place of oil sloould be used in the final coat of paint when intended to le varnished. The process is then similar to that described for new woodwork, c.scept that it is unnecessary to size the work.
For old painted work, the surface should he cleaned with water to which is added soda.
and any nail holes or other inclentations filled in with putty toned to the required lue with colours ground in oil. Tho putty is applied with a linife, care bcing taken not to smear the surrounding surface and to smonth it. If soda is used to clean the work, it should be well rinsel off afterwards with clean water and thoroughly dried. The varnishing may then be carried out.

Treating a Floor. A task which often falls to the home worker is the varnishing of a floor. If the boards are quite hare, it will probably be desired to stain then first. The whole lloor, or that part of it to be varnished, should be lirst well scrubbed, and when dry given a coating of size, and once dgain left to dry. It is then smootherl down with fine glass paper, and all dust removed, first with a brush and linally with a cotton duster. The area can then be coloured as described in the article on Stain. Assuming an oil stain has becn used, a varnish with a similar composition can be employed in much the same inanner as described for other work

The varnish is used frcely, and is well worked out, especially at the corners. The best method is to conimence at one side and work towards the door when the whole lloor is to be coated as otherwise it may be impossible to leave the room without treading on the wet varnish, If two coats are desired the first should be allowed to set first, and is then felted down and lusted before the sccond, in the manner described above.

In cases where a large area has to be dealt with it may be worth while using one of the clear cellulose varnishes. applicd by a spray. A portable sprayer with foot pump can be obtained for a quite small outlay, and would soon pay for itsclf on the many and varied johs for which it is suitable. Information on these points will be found in the articles Enamel and Sprayer.

VASE. Though vases may be of chinn, pottery, marble, jade or other semi-precious stones, of gold, silver, brass,
 of sait, and if they are luted, or in any way difficult to reach with a cloth or the hand, a brush or small mop should be used for the purpose. See China, Copen hagen Ware ; Crown Derby ; Flowers; Garden Furniture Glass Ware; Jisper Ware : Pottery; Satsuma Ware Sealing Wax.

VASELINE, One of the most uscful remedies extensively employed in the home for chapped slin and for various other purposes is vaselinc, which is a greasy, whitish-yellow, semi-solid

Vase. Fig. 1. Ancient Roman onvx vase in a $12 t_{\text {a }}$ 15th or 16 th century, bearing en abbresiated inscription. Fig. 3. Reproduction of a silver Georgian vase. Fig. 4. Cut glass vasc of delicate and beautiful workmanship Fig 1. hin hermassion of the Director, Victorind and Albert Museum. S Kensinglon; Fig 4. Un courtesy of Cecil dirts
bronze, lead or pewter, of glass or papiermâché, the classical shapes continue to serve as morlels even when new forms of clecoration are introduced or applied. A glance at our illustrations of beautiful pieces, varying in styles and periods, reveals familiar shapes seen in vases made to-day of ordinary wares, except that Fig. 4 is often copied or adapted in cut glass without the lid.

Richly ornamented, precious metal, or gennine antique vascs are either collectors' picces or have a decorative value only Apart from the risli of damage or breakage they are not usually even effective as llower vases. For this purpose reproductions in plainer styles of pottery and glass of the classical shapes are most satisfactory. Two other shapes are popular: the straight jar for long stemmed flowers and the globe in glass with a small opening in which it is easy to arrange a few fine blooms.

For table clecoration one or two scts of tour small vases in iridescent, cut, coloured or engraved glass, in white ware, in green or brown pottery, silver or silver lustre are uscful. Whether small or large, llower vases should be shaped so that proportionately they hold plenty of water.

Glass vases need attention if they are to he kept bright and clearr. 'Jhey are very casily stained by flowers, and soap and water is not always sufficient to remove these stains. They should be cleaned periodically with a little spirit of salt, and if they are
 .
paraffin. It is a useful basis for certain ointments, as it does not become rancid.

VAULTING HORSE. As used in gymnastic exercises, the vaulting horse is made of wood suitably padded and covered with leather and supported on wooden legs which are adjustable as to height. A typical vaulting horse is illustrated in Fig. 1. It has $\Omega$ total length of 6 ft ., n width nt the top of 16 in ., and

Vaulting Horse. Fig. 1. Gymnastic uppliance which is adjustable to various beights
a height, without cxtension, of ahout 3 ft .3 in . The curved handles, known as pommels, are fitted in the centre, the portion of the horse between the pommels being the saddle. The left-hand pommel is the neck pommel (N.P.), and the left-hand end of the horse is the neck ( N. ). The right-hand pommel is the croup pommel (C.P.), and the right-hand end of the horse the croup (C.).
The horse is generally used with a spring hoard, referred to also as the bcating board. When the performer is standing so that the shoulders are parallel to the side of the horse, the horse itself is called side horse or horse sideways. Positions in which the line of the shoulders is at right angles to the length of the horse are called cross positions. The side of the horse at which the spring stands is the near side, and the side farthest awny from the board the off side.

The whole of the upper portion of the horse is covered with hide, and the pommels, which are $17 \frac{1}{2}$ in. apart, $4 \frac{3}{4} \mathrm{in}$. above the sadille, $1 \frac{1}{2}$ in. diameter, and $4 \frac{1}{2}$ in. circumference, are of iron covercd with leather, Hesh side outside, tightly sewn to the metal. The ponimels are removable and are attached by large flynuts undernenth the saddle. Exercises on the vaulting horse arc brgun with or without a run. but are always finished in the half-squat

Fig. 2. Smaller anpliance known as a vaulting buck. It is preferable in small gymnasiums
position prior to the upright position. The pominels are generally grasped with the hands, back upward, known as the pike grasp, with the palms of the hands slightly beyond the centre of the pominels towards the off side of the horse.
There are less expensive alternatives to the vaulting horse, such as the vaulting buck, in Fig. ${ }^{2}$. It consists ol a padded top covered

## Veal and How to Cook It

## With a Selection of Attractive Recipes

The reader of this article will also be interested in those that describe other ioints of meats, e.g. Beef; Mutton; and other items of houschold food. See also Bacon; Boning; Brawn; Curry; Food; Forcemeat; Pastry; Soup; Stuffing

The Hesh of the calf is closer in texture than weiglit. Chop the bones so that the breast may beef or mutton, and on this account it has been be dividerl into small pieces, and remove all said to be less digestible, but when pro perly gristle. Put into a frying-pan about 4 oz. handled in the kitchen it is one of the most butter and bacon fat mised together Floui nutritious and palatable of meats. Veal must the pieces of real and fry them in the fat till he eaten while fresh and reyuires to be well and judiciously Havoured with a stuffing or lemon, otherwise it is rather tasteless. Bacon or ham should accompany it to make up for the absence of fat.

Veal may be eaten in some forms by invalids Excellent broth is made from veal and also meat stock for white soups. The superior flavour of calf's head, liver, sweetbrearl. etc., is well known, whilc. the suet surrounding the kidney is particularly arlapted for light boileil puddings or forcemeats.

The calf, when it is killeıl, should be 8 or ! weeks old, and never more than 12 weeks. The best roasting pieces are the fillet, loin, and neck, and occasionally the oyster part of the shoulder. For cooking, 20 min . to the lb . is the correct average time.

A fillet of veal from a calf 8 weeks old should weigh just $12 \mathrm{lb} .$, but the butcher will always divide it into two or more portions. It is an economical joint, as there is very little bone and no waste. Before roasting, the centre piece of hone must be removed and the cavity filled with a well Havoured veal stuffing, of which lemon is always a feature. The stuffing must be well secured in the meat either by binding the joint together by tape or skewering it. Loins and necks of veal are not boned before being roasted, but the bones must be jointed carefully. The stuffing should be inserted by separating the skin from the llank from end to end with a sharp knife and forcing it in place, then it should be secured with string.
The outer slin of veal should be protected with a huttered paper or a piece of the canl, and when the joint is almost cooked the protecting paper should be removed, the surface dredgod with flour, well hasted, and the outside allowed to brown. Veal must be basted frequently while cooking with butter or good dripping provided for the purpose, as the meat possesses little or no fat. Bacon or ham should always accompany roast veal.

Veal Hotch-Potch. Breast of veal makes a good hotch potch. Use a piece about 5 lb . in
a light brown, then put them into a casserole and pour on them - quarts boiling water. Let all boil up, then add 1 pint green peas, a well-washed cos lettuce cut in strips, 2 blades of mace, 3 cloves and 15 black peppercorns tied up in a piece of muslin, a bouquet garni,
 and 2 onions cut in rings.

Season with salt and simmer for 3 hours. Before serving remove the bouquet and the bag of spices. In winter-time sprouts or the hearts of small savoy cabbages and celery cut small may be substituted for the green peas and lettuce.

Knuckle of Veal. This may be boiled or stewed, but much depends on the cut of the joint and how much meat accompanies the knuckle. If cut very low down in the leg, always stew it. A joint of 6 lb . will take from 2 to $2!$ hours to boil, but much longer in proportion for stewing, even if only 3 to 4 lb . in weight. Veal must always be cooked in plenty of water when boiled: it must be carefully skimmed and amply flavoured with vegetables. When dished, a sance should be poured over it into which part of the liquor in which the meat was cooked should he introduced. A small quantity of milk will whiten the sauce and soften it, and it may be tinished with parsley, hardboiled eggs, or, if preferred, it may be left plain.

Veal is a useful meat as the remains of cold joints can be made up into a number of excellent luncheon diahes and entrées. It curries and minces well, makes good rissoles and quenelles, and is excellent in such cold supper dishes as brawn, Cornish pastics, pies, and patties. Recipes for these veal dishes, or recipes which may equally well be adapted to the use of veal, are given under the various headings.
Veal and Ham Croquette. Nince fincly $\frac{1}{2} \mathrm{lb}$. cooked veal and hain mixed, allowing a bout $\hat{6} \mathrm{oz}$. veal to 2 oz . ham. Add 2 teaspoonfuls grated onion, the same chopped parsley. and a smiall teaspoonful grated lemon-rind. Mix all these to a crenmy consistency witl about l gill hot, thick white sauce, and senson carefully. Turn the nixture on to a plate to cool, shape it into even-sized shapes, such as balls, ovals, pear or cork shapes. Roll these in fine white
crumbs, then brush them over with well-beaten egg and give them a second coating of crumbs. Fry the croquettes in plenty of smoking hot fat. Drain, and serve on a fancy dish paper, garnishing with fried parsley.

Veal and Ham Pie. Make some flaky prstry according to the directions given in the general article on Pastry. Roll out to required thickness. Cut $1 \frac{1}{2} \mathrm{lb}$. lean veal and $\frac{1}{2} \mathrm{lb}$. lean ham into neat squares, slice 2 or 3 hard-boiled eggs, and use the slices to ornament the sides and

each of salt, pepper, and nutmeg Remove all the bones and tendons from the meat and spread it, with the skin downward, on the table. Season the meat carcfully with salt, pepper and a little nutmeg Next remove the skin from the sausages, season the sausage meat, and spread half of it evenly over the veal. Cut the ham and eggs in long strips, and arrange them alternately and evenly down the length of the veal so that when it is rolled up the strips run from end to end.

Season the veal again and then spread on the rest of the sausage mixture. Roll up the veal neatly !rom side to side and tie it up in a cloth like a roly-poly pudding. Put it in the stock pot and let it simmer gently for 2 or 3 hours. Then untie the cloth re-roll the meat in it, and place it between two tins or dishes with weights placed at even distances on the top one Leave it until it is quite cold, then take off the cloth, trim a small piece off each end, and brush it all over with a little melted glaze
Veal Goulash. This stew is made by slicing a large onion into thin rings, frying it in a rings, frying it in a dice.
 bottom of the dish, pressing veal on top, and shake over it a little chopped parsley and some powdered mixed herbs, a little grated lemon-rind and seasoning to taste. Cover these with a layer of ham and continue thus until the dish is full. The last layer should be of ham. Pour in some stock, preferably made from veal bones, half filling the dish with it. Damp the edge of the dish, lay a strip of pastry on it, damp this also, and then cover the pie with the pastry. ornamenting the top with pastry leaves and tassel.

Bake the pic in a hot oven for ahout two hours. In hot weather a little gelatine should be added to the stock so that it is certain to set in a jelly. To make a raised veal and ham pie see directions for pork pie and the illustration of pie mould in

## pages 985-986.

Veal Forcemeat. Suet is an important in- stewpan, containing gredient in stuffing for veal as the fat is $1 \frac{1}{2}$ oz. dripping, and essential; l oz. shrealded suet should be when it is lightly allowed to $\frac{1}{2}$ oz. breadcrumbs. Chop 4 oz. browned adding shredded suet finely, mix with it 6 oz . bread- $1 \frac{1}{2} \mathrm{lb}$. leau veal cut crumbs, 1 tablespoonful finely chopped parsley. the grated rind of a lemon, 1 teaspoonful mixed herbs, 1 dessertapoonful lemon-juice, 1 pinch nutmeg, pepper and salt to taste, 2 rashers fat bacon minced finely. These ingredients are bound together with a beaten egg and a little milk.

The stuffing when made can either be pressed inside the joint to be stuffed, or, if preferred, formed into balls rolled in flour and baked in the oven.
Veal Galantine. To male this, take a small breast of veal, 2 lb . pork sausages, $\frac{1}{2} \mathrm{lb}$. cooked bam or bacon. 3 hard-boiled eggs, with a little
into small squares and freed from skin I'ut the lid on the pan and cook the meat until it has lost its rawness; then spinkle in 13 oz. flour and seasoning to taste, stirring the whole well so that the flour is mixed thoroughly. Pour in about a teacupful of stock and a large
glassful of Madeira. and cover the pan again. simmering its contents at the side of the stove, stirring them now and again to prevent burn. ing, and adding more stock if the stew becomes too dry. The time required for cooking is about 2 hours. Half an hour before the stew has finished cooking add four average-sized potatoes cut into small cubes.
Veal Mould. This very serviceable and appetizing dish can be made from l lb . un. cooked veal, 2 hard-boiled eggs. 4 oz . bacon, a little grated lemon-rind some mixed herbs, and a little parsley finely chopped. A little seasoning, some salad for garnishing, and a pint of white stock are also necessary.
Grease a mould slightly, cut one egg into slices, and with it decorate the bottom and sides of the mould Remove any skin or gristle from the veal and cut it and the bacon into small dice; then chop up the other egg. Mix the veal, bacon, egg, herbs, and lemon-rind together, add a little parsley and season it with pepper and salt. Place this in the prepared mould, taking care not to pack it too tightly and moisten each !ayer with seasoned stock.
Cover the mould with a greased paper, place the tin on a baking sheet. and cook it in a moderate oven for $1 \frac{1}{4}$ or $1 \frac{1}{2}$ hours. Then remove it from the oven and fill up the mould with some warmed and seasoned stock. When it is cold and set, dip the mould in hot water and turn the contents into a dish Garnish it with a little green salad composed of lettuce, endive, and cress, season it with pepper and salt, and sprinkle a few drops of Icmon-juice over it.

Veal Pudding. Make l lb. suet crust (q. v.). Cut 2 lb . lean veal and 4 oz . ham into small dice. Grease a pudding-basin, roll out twothirds of the pastry, and line the hasin with it. Put in a layer of real and ham, sprinkle over them a little chopped parsley, grated lemon-rind, and seasoning to taste, and then cover them with some slices of hard-boiled egg; 2 eggs should be sufficient. Continue until the basin is full, and then pour in a gill of water.

Roll out the remainder of the pastry to fit the top of the basin, wet the edges, and put it on, pressing it well. Tie a pudding-cloth over the basin, and then put the latter into a pan of boiling water. Boil for two hours, adding more boiling water when necessary:
Veal Ragoût. This stew may be cooked and served in a casserole. Cut 2 or 3 thin rashers of fat bacon into small pieces, fry them lightly in an earthenware casserole, and then add an onion cut into thin rings. Cook this without browning it for a few minutes, and then put in I lb. veal, previousily freed from skin and bone and cut into pieces of a convenient size, a bunch of mixed herbs, a little shredded celery, and seasoning to taste. Add also 1 teacupfnl stock; then cover the pan and cook its contents at the side of the fire or in a cool oven for about 2 hours or until the meat is tender. When it is cooked take nut the herbs.

# Vegetables and Vegetarian Cookery 

Directions for Preparation and Recipes for Appetizing Dishes

n addition to this article, which deals with vegetables in general and the main principles of Vegetarian Cookery, our work contains entries on the different vegetables, e.g. Cabbage; Celery Onion; Potato. See also Casserole; Diet; Food; Kitchen Garden; Pastry

In gardening the name of vegetable is given to those plants which have edible roots, stems, shoots, flowers, or leaves. Vegetables arc divided into the following chief classes, examples being given of each: Legume-pens and beans: edible rooted-beet, turnip, onion. potato; salads-endive, lettuce, mustard, and cress: vegetables which are really fruitstomatoes, vegetable marrows, cucumbers and capsicums. Cabbage, kale, Brussels sprouts and asparagus are valued for their leaves or shoots, chicory and seakale for their blanched growth, rhubarb and celery for their leaf stalks, and cauliflower and broccoli for the edible flower heads. The mushroom is invariably classed ns a vegetable, although it is really a fungus. Herbs such as parsley, sage, thyme, and other savoury flavourings are usually classed among the vegetables.

Methods of Cooking. The time for boiling vcgetables varies. The Cook's Time-table (given in back cover Part 13) should be consulted Salted water must always be used, the proportion being 1 oz . salt to each gallon of water. Most vegetables should be plunged into fast-boiling water, old potatoes and onions excepted. Old potatoes require cold water, and should not be cooked too fast. New potatoes should be cooked in hot water

Jerusalem artichokes, salsify, and roots of a like character may be cooked partly with milk. An acid, such as lemon-juice, should be added.

Blanched vegetables-seakale, celery, etc.require careful handling, and are usually tied in bundles before being boiled. They are served on toast, being soft and watery. Asparagus is also tied and served on toast.

Onions are better if they are blanched before boiling, that is, if they are boiled up and allowed to cook about 10 min ., then the water thrown a way, cold water poured on them, and finished in the second water. If treated thus they will be whiter and a finer flavour. Leeks are cooked like onions, but are easier to dish if tied in bundles for cooking. All dried pulse must be soaked for at least 12 hours before being cooked, and must be carcfully picked over.

When soaking greens to revive them from packing or handling, add no salt to the water until they have freshened up a little, then change the water and salt it. They should remain about 20 min . without salt. After being thoroughly cleaned they should be plunged in plenty of fast-boiling water and salted according to the directions given.
Green vegetables should be boiled with the lid off the pan to keep their colour. Common soda should never be added to soften hard water. A pinch of bicarbonate of soda may be us 3 d with an enamelled pan or carthenware casserole; not.with aluminium warc. Many salad herbs may be boiled and served as green vegetables. Lettuce particularly is adapted for this purpose. As soon as the vegetables are cooked they should be drained in a strainer or colander, otherwise they absorb water, lose flavour and become discoloured.

It should be the first aim of the cook to preserve as completely as possible the healthgiving salts in vegetables. The usual method of boiling vegetables is too often uneconomical, unwholesome, and destructive of Havour The more hygienic method is steaming.
All the garden roots arc more palatable and wholesome when steamed. There is great loss in boiling carrots, parsnips, and turnips. The nutrients are not abundant in these vegetables, and after boiling only a small residuc remains. Artichokes and beetroot may be steamed, and the taste will be improved. The starch and
sugar in parsnips and carrots is much wasted by boiling. When large roots are steamed they should be cut into portions. Small carrots, turnips, parsnips, and beetroots can be steanied whole. A little salt should be sprinkled over all vegetables before cooking.
Drying of Vegetables. Vegetables are dried commercially by machinery, but the housewife may dry small quantities in the oven. Drying trays may be purchased ready made, or may be constructed by nailing together in a square four wooden laths, and stretching wire gauze across the framework. Vegetables should not be put on the iron trays of the oven. Drying must be done only in a moderately warm oven. After the oven has been used for cooking, take out the oven shelf, put in the drying tray with its charge of vegetables, and leave it all night, with the oven door ajar. On the following morning remove the tray, but if the contents are not dry, put it back in the oven in the evening.
The warm, dry air arising from the kitchen fire may be used for drying fruit and vegetables. The drying tray may be placed on the plate rack, or, if the fire is low, the tray may be hung below the rack. In tbe casc of old-fashioned fireplaces, with the chimney opening immediately over the fire, the tray must be placed sufficiently in front to prevent smoke from passing through the tray, for although the fumes of charcoal, coke, or gas will not cause the dry material to taste, coal or wood smoke will do so. In all cascs the heat must not be sufficient to scorch the vegetables.
Carrots, parsnips, turnips, swedes, and beet need peeling and scraping in order to remove the outer skin. They should then be cut into slices $\frac{3}{16}$ in. thick, or into shreds by means of a hand grater. Steam them for a few minutes, then place them thinly on the tray and transfer them to the oven. The temperature must not exceed $160^{\circ} \mathrm{F}$., otherwise the vegetables will brown. With onions, to avoid the unplcasantness of peeling, immerse them in boiling water for a minute. Then peel and slice them, but do not stcam them before drying them as the other vcgetables mentioned. Leeks should bc treated in the same way, except that they should not be placed in boiling water.

Vegetable Rack. Convenient type of wire ract for the small larder which allows for access of air to the

Spinach, parsley, or mint should be blanched by plunging them into boiling water to which has been added a iittle bicarbonatc of soda, until well scalded. Cool in cold water, drain, and spread on the drying trays. The more quickly these are dried the better the colour is retained, but when drying rapidly they should be watched closely to prevent scorching. These may be dried without blanching, but the colour is not usually so good. Green peas should be well developed but not old. After shelling, put them into a saucepan with some good sprigs of mint, a little salt and a pinch of bicarbonate of soda, cover with cold water, and bring to the boil, or they may be plunged into boiling water and retained there for a few minutes. Finally, cool them in cold water drain, spread evenly on trays, and dry until quite firm.

With runner beans sclect those that are not quite full grown, string and slice, then blanch and cool the same as for peas, but without mint. Spread on the trays to a depth of about $\frac{1}{2}$ in., and when well warmed move them about occasionally to allow the air to circulate freely. When the pieces break upon bending them with the fingers they are quite dry. As regards broad beans, shell well-dcveloped but not old ones. Blanch them in plain boiling water in the same way as peas, and dry them until they become like seed beans.
Celery may be dried in the long leaf or cut up into small picces. It is improved by blanching, although this process is not really necessary. The green outside leaves arc also excellent for flavouring when dried, but these should be blanched like runner beans. Thyme and sage should be dried slowly, at a warm teinperature, or simply hung up in bunches in a warm, airy place

When soaking vegetables for use, a little bicarbonate of soda added to the water will assist them to regain size more quickly.

To store them, the best way is to put the dry vegetables in stout brown paper bage and to hang the bags in the kitchen. If no thoroughly dry room is available, store them in tins or in airtight bottles.

During spring and sumner, when fresh vegetables are plentiful, it is a wise plan to bottle some of them for winter use. A simple outfit is illustrated in page 1008.

Vegetable Presser. Constructed from a good hardwood, the presser is employed to remove the surplus water from vegetables which have bcen placed for the purpose in a colander. These pressers are obtainable in turned wood with a flat and a slightly domed surface.
Vegetable Rack. Racks for the storing of vegetables are made in wood and in metal. An inexpensive, clean and convenient type of wire rack for the small larder is here illustrated. The air is able to reach all the contents of the rack and to keep them fresh and crisper than when stored in wooden trays. The racks are obtainable enamelled in colours.

Vegetarian Cookery. Vegetarian dishes should not be principally composed of vegetables, as excess of the everyday vegetable will cause Hatulence. Nuts, cereals and, where they are included in the diet, eggs and checse are all uscful as main ingredients for thesc dishes. Peas and beans seem nore easily digested if taken in a moist form and if mashed or made into a puréc. Hence pea or bean soup is both wholcsome and agrecable, but, on the other hand, pease pudding or a dish of plain boiled beans will prove indigestible to some persons.

The swect course in a vegetarian dinner or luncheon may be much the same as that for a meat meal, only no suet or lard may be used in the preparation of puddings or pastry, neither may lard be used for any kind of cakes or even for greasing tins. Vegetable butter or real butter is the only fat permissible. Oil is the best medium for frying.

Freah salad herbs should form part of the meal where foods somewhat deficient in mineral salts are the principal dish, pulse foods, for instance. If salad is difficult to obtain, the use of lemons is recommended: oranges also are beneficial, while grapes contain the necessary health salts. Many excellent recipes for salads are given under that heading

Dried fruits such as dates, prunes, raisins, and fige are nourishing and useful in the pre paration of many dishes. Nuts are usually ground, particularly if they are to be added to other ingredients, and a nut mill can be bought for this purpose. Cheese is a strength. giving food and therefore most valuable where meat is omitted. For persons of sedentary habits it is more digestible if grated or cut in small pieces and mixed with other ingredicnts.

Specimen Menus. The following are two specimen menus for a vegetarian meal, the first being suitable for winter and the other for summer

No. 1
Salsify Soup
Lentil Stew
Cauliflower au Gratin. Mashed Potatoes Orange and Chestnut Cream

Dessert
No. 2
Tomato Soup
Haricot Bean Cutlets
Green Peas Cherry Pie

## Dessert

Salsify soup is made like ordinary white soup, except that the necessary liquid or stock consists of water and 1 milk. The lentil stew is inade by soaking overnight and preparing 1 pint red lentils, then stirring them for 5 min . in 2 oz . butter which has been melted in a stewpan. Add l quart cold water, and when all boils up put in 2 onions, 3 sticks celery, 2 carrots (all prepared and cut small), 1 teaspoonful grated lemon-rind, and seasoning. Simmer for $1 \frac{3}{4}$ hours, then stir in 1 oz . barley flour mixed to a thin paste, also 1 tablespoonful chopped parsley and the same of red currant jelly. Cook again for 15 to 20 min ., when the stew should be thick enough. Serve it with croûtons of fried bread or toast.
Orange and chestnut cream is made with chestnut puree and sections of oranges pecled and pipped and tossed in a strong syrup. The purée and oranges should be piled in alternate layers on a dish and masked with whipped and sweetened cream.
In the summer menu the tomato soup differs little from an ordinary tomato soup, except that bacon is omitted and bran stock is substituted for the meat stock. This is made by pouring 1 quart boiling water over 2 tablespoonfuls bran, letting it stand till cold, and then straining it. A small quantity of creain should be boiled up in the soup just before serving it, and it should be well seasoned.

Haricot bean cutlets are made by cooking 1 pint white haricot beans with 4 shallots till tender, then chopping them fine. A thick sauce must then be made, using $1 \frac{1}{2} \mathrm{oz}$. butter, $1 \frac{1}{2}$ on. Hour, 1 gill water that beans are boiled in, and 1 gill milk or cream. Season the sauce well, add the beans, 1 tablespoonful prepared and chopped mushrooms, $\frac{1}{4}$ teaspoonful each mace and lemon-juice, and a little chopped parsley, and mix all together. When cold, shape into cutlets, egg, crumb, and fry in boiling oil. Serve with horseradish sauce.

Many savoury vegetarian dishes may be made by using Italian pastes, macaroni, vermicelli, spaghetti and noodles as a foundation, including also Tagliatelli. For this make a smooth, firm dough with 1 lb . Hour, 5 eggs, 1 oz. butter, salt, and warm water as requircd. Roll out the paste $\frac{1}{18}$ in.
thick, let it set, and then lold it over and over flouring it to prevent sticking. Cut it into shreds and poach for 6 min . in salted water.

Porridge is useful as a breakfast dish. An uncoinmon kind to-day is the old-fashioned frumenty, a wheatmeal porridge llavoured with raisins and cooked in a jar in the oven for several hours. Gelatine must not be used in vegetarian cookery. Aga-aga is sometimes substituted, but it is not recommended for general purposes. Recipes for vegetable cur ries are given in the general article on Curry
Galantine. Excellent vegetarian entrées are made of nuts, onions, or lentils as the basic ingredient. Nuts of any kind and breadcrumbs, boiled rice or mashed potatocs form the main ingredients of a good galantine. It is inade by shelling and blanching 3 oz . nuts, skinning them, and putting them through a mincing machine. To this mince add $\frac{1}{2} \mathrm{lb}$. breadcrumbs, or the same quantity of rice or potatoes, a finely minced onion, and 1 teaspoonful each of chopped parsley and mixed herbs. Season the mixture well, and bind it with 1 gill stiff white or tomato sauce, and the well-beaten yolks of two eggs.
Shape the whole to form a large sausage Put it into a scalaed floured cloth, tie the ends securely and place it in a saucepan of boiling water. Let it simmer for $1 \frac{1}{2}$ hours, put it on a dish, remove the cloth, and press the galantine between two tins with a weight on top. Leave it until it is cold, then trim the ends neatly and brush it over with glaze.

Lentil Cake. The ingredients for a lentil cake are $\frac{1}{2} \mathrm{lb}$. cooked lentils, $\frac{1}{2} \mathrm{lb}$. cooked potatoes, 1 oz. margarine, $\frac{1}{\frac{1}{2}}$ teaspoonful powdercd herbs, a teaspoonful each of chopped parsley, grated onion. flour, milk, breadcrumbs, and frying with a little salt and pepper.
The lentils, which should not be watery, should be rubbed through a sieve with the potatces. Then melt the margarine add the lentils, potatocs, herbs, parsley and onion, after which the whole should be heated, seasoned and mixed well together. Turn the mixture on to a plate to cool, and make it into small flat cakes on a floured hoard. They should he brushed over with milk, coated with breadcrumbs and fried in hot fat. When ready, drain them on soft paper and serve them on $\Omega$ hot dish garnished with fried parsley.

The cakes will be improved if a beaten egg is added to the mixture while it is being heated. Another way is to place on each calie either a poached egg or half a hard boiled one with the cut end downwards, the egg being coated with tomato sauce.
Onion Pudding. To make an appetizing onion dish, take six small Spanish onions, 1 breakfastcupful breadcrumbs, an egg, a little milk, and some brown gravy, together with 1 dessertspoonful melted butter, a little grated lemon-rind, a pinch of nutmeg, and a little pepper and salt. Slice the onions and fry them to a golden brown, and then line a small pudding basin with them. Mix the bread. crumbs, the egg, which has been well beaten, the butter, nutmeg, and lemon-rind together: add the pepper and salt, and mix all thoroughly with a little milk. Pour this mixture over the onions and steam it for $1 \frac{1}{2}$ hours. The gravy should be heated and used for serving with it.
Vegetable Patty. Cooked vegetables. such as carrots, turnips, pas, etc., can be made into patties in the following way: Line some greased patty pans with short pastry, using butter instead of lard, as given in the recipe in page 912 , or half butter and half margarine, fill the cases with rice so as to prevent them from rising in the centre, and then bake them in a hot oven until they are lightly browned. Bake also some strips of pastry shaped like handles. In the meantime, cut all the vege-
tables, except the peas into small dice heat them up in a little thick white sauce and season them to taste

When the pastry cases are cooked take out the rice and turn them out of the pans, fill them up with the hot vegetable mixture and fix a handle to each, using a little raw white of egg to fasten these to the sides. Serve the pattics at once. They are better caten hot than cold

Vegetable Pie. A hot vegetable pie can be made thus: melt 1 oz. margarine in a small pan, add 2 -tablespoonfuls chopped onion and fry these to a pale brown colour before pouring in 1 gill brown sauce or gravy. Simmer the whole for about 4 min ., then add $\frac{1}{} \mathrm{lb}$. cooked macaroni cut into small pieces and 2 oz . grated chcese.

Break a small cooked cauliflower into sprays. and peel and slice 3 tomatoes and 4 large mushrooms. Arrange these in !ayers in a well-greased pie-dish. cover them with the macaroni and sauce, and then put on a lid of short-crust pastry. Decorate the edges with a knife, ornament the to $p$ with pastry leaves, and then bake the pie in a hot oven until it is lightly browned. Serve it in the dish in which it is cooked.
VEGETABLE MARROW. This is the full name for the vegetable more usually known as the marrow, hints on the growing of which and recipes for marrow dishes are given in page 773 . See Marrow.
VELLUM : How to Mount. Vellum is the name given to parchment made from the skin of young calves and lambs, which is exceedingly durable, and is used for legal documents, bookhinding, and for illuminated nddresses. It is finished with an ivorine appearance and is unequalled as a surface for lampshades and other articles for which mitation vellum or vellum paper is generally used. Vellum can be stained by first soaking it in water and then dipping it in a chemical or vegctable dye, but it is advisable to test the effect of the dye on a scrap of the material before attempting a whole skin, as dyes differ widely in their action.

In the preparation of vellum for writing or illuminating considerablo care is required, and although it is often stretched on a board by professional workers, the better plan for the amateur is to mount it on a suitable board. The materials required are a sheet of mounting board of the thickness known as 8 sheet, a basin in which hot water is placed, covered by a saucer, two teaspoonfuls of seccotine and two of hot water being mixed together in the saucer, a basin of cold water, some sheets of clean white paper and some greaseproof paper or thin vegetable parchment, two pieces of clean linen about the size of a handkerchicf, two small sponges, some fine pumice powder, two Hat boards, a piece of heavy cardboard, and some weights for the purpose of keeping the mounted vellum under steady pressure.

First of all the vellum is placed right side up on a shcet of clean paper and thoroughly clamped with a sponge with cold water; the surplus water is wiped off with one of the linen cloths, and then the vellum is turned over and the same procedure carried out on the other side. Wipe off the surplus moisture as before, and then dip the other sponge in the seccotine mixture and thoroughly cover the back, taking care that the extreme edges are covered with the scccotine.

The vellum is now lifted up and placed in the centrc of the mount, with the edges quite square. Beginning at the top, the surface is stroked down with a clean linen cloth to remove the air from underneath and to bring the material into the closest contact with the mount. A sheet of clean white paper is placed on the top of the vellum, the cardboard is laid over it, and the mounted work
is put between two boards with the weights on top. The vellum should be kept under pressure for at least twelve hours in order to allow it to dry quite firm and even before decorating it.
The material is now ready, and should be dusted over with some fine pumice powder, but on no account should it be touched with the fingers. The design or lettering to be placed on the vellum is first drawn out on a piece of thin paper as carefully as possible. The back of the paper is rubbed over with blacklead and thoroughly rubbed in with a picce of rag. The drawing is placed in position, a a the lines transferred to the vellum with an agate tracer or fine stylo, only the thinnest line being required. Ordinary carbon transfer paper is not suitable for use with vellum, owing to its greasy nature and the liability of making other marks caused by the pressure of the fingers on the paper while working.
For the ink work, a waterproof Indian ink should be used. A ruling pen should be employed for straight lines and other lines that can be drawn with a compass; for freehand lines and lettering a fine drawing-pen is required. Colouring is done with the best quality of water colours mixed with a little gum arabic. Gold can be applied, but it should be shell gold and mixed with gum arabic. For silver effects it is better to use aluminium in the same way as the gold, as it is not liable to tarnish as is the case with silver. Lines can be rubbed out with putty rubber.
Scraps of vellum hoiled down make an excellent size for applying gold-leaf, and this is the material generally used. For the purposes of bookbinding there are several kinds of vellum available. Prepared or artist's vellum is prepared in the natural colour of the skin. Roman vellum is similar but darker; it is always attached to the boards with the flesh side downward. Vellum can be cleaned with benzine applied with a sponge, stains being removed in this way without destroying the texture. See Bookbinding; Lampshade.
VELOUR: The Material. The French name for velvet is given in Great Britain both to wool and cot ton plain cloths made with a short and more or less velvety nap, which is produced by finishing the cloth in a special manner. This nap is soft to the touch, and it enriches the colour, lending a peach-like bloom.

Wool velour cloths sometimes show a fancy design, and are known as jacquard velours where the design is woven. Sometimes the pattern is mercly embossed and therefore less permanent.
Cotton velour, which makes rich-looking curtains, showing a double tone of colour, is obtainable in a finc range of colours, warranted not to fade.
VELOUR HAT. Made essentially for winter wear, velour hats are manufactured from hare fur on a foundation of soft felt. The better qualities have a silky, plush-like surface, and Austrian velours, which are the finest of all, are among the most expensive and durable of hats. The cheaper kinds, and especially the imitation velours, wear badly, and quickly lose their shape.
VELTHEIMIA. This is a South African bulb suitable for cultivation in pots in the greenhouse or in a warm sheltered border out of doors. A suitable compost consists of loamy soil with a little leaf-mould, decayed manure and sand. The chief kind is Veltheimia viridiflora, with rich green leaves and pale rose-coloured Howers in summer on a stem 12 in. or more high.
VELVET. Millinery velvet is usually narrow. Collar velvet is a specially dense and fine fabr:c, built for hard wear. Old-fashioned
dress velvet was a warm, hard-wearing silk pile fabric which is not much uscd nowadays. The chiffon and ring velvets are made with a lighter and more open pilc. They hang in graccful folds, and have a soft. rich and glossy surface in which the separate rows of tufts can often be scen.
The most exquisite shades can be dyed on silk velvet and no fabric shows off a fine
 velvet has to be turned down and bemmed
colour to greater advantage. The mohair velvets or moquettes are used largely in place of silk velvet for upholstery.

When cutting velvet for nillinery and trimmings care should be taken to cut it on the cross, otherwise there may be trouble in getting it to lie flat. Velvet can be freshened in appearance by steaming with a hot iron. The face of the iron should be turned uppermost and the velvet passed over the surface by hand. Cuttings of velvet should always

## Veneering for the Amateur Cabinet Maker

## A Decorative and Useful Method of Surface Treatment

In this work are associated articles, ealing with Inlaying and Marquetry. The use of veneers in renovating old furniture is explained in the article on Chest of Drawers. See also Cabinet
Maxi..g; Dressing Table; Sofa; Wardrobe

Vencering is the process of applying a comparatively thin sheet of wood of fine or rare quality to a groundwork of a plainer variety of wood. It thus enables many beautiful woods to be employed for decorative work which are prone to twist or crack if made use of in the solid. A typical example is the employment of curls and burrs, which would prove com pletely unsatisfactory unless applied in the form of veneers.

It is also the only satisfactory method of employing such decorative effects as quartering, balanced matching of grain, and other flat treatments in which the work relies for its effect upon the disposition of various woods, the grain of which runs in contrary directions. In shaped work veneering is almost indispens able. To cut the wood in the solid would entail a certain amount of end graining showing, an undesirable feature in itsclf owing to its exhibiting no beauty of grain and the fact that it does not polish well. Also it would involve weakness of construction.

There are two kinds of veneer, known as knife and saw cut, according to the instrument employed. Knife cut is the thinner of the two and is cut by one of two methods, cither

Veneering. Fig. 1. Cutting knife-cut veneer with a veneer gaw worked againsi a atraight edge
rotary or flat. In the former a $\log$ is placed in a structure similar in principle to a lathe and having a long knife edge stretching along its whole length. The knife is adjusted to cut the required thickness and moves forward against the $\log$ as it revolves, thus cutting a veneer the same length as the $\log$ and of practically unlimited width.
This method has the effect of giving a very enlarged grain, and is impracticable when, for example, a wood is to be cut which relies for its appearance upon the medullary rays, as in figured oak. for which the Hat-knife method is adopted. The finer woods are cut in this way, a machine similar to a plane taking off venecrs. Saw-cut vencers run from $\frac{1}{32}$ in. to $\frac{1}{18}$ in and are cut with a circular saw, all such woods as curls being cut by this method.
Preparing the Ground. A very important considcration in veneering is the ground to which it is to be applied. The wood should be

as straight in the grain as possible, clean and dry, and with the least tendency to warp and shrink. For these reasons Honduras mahogany is the most suitable, as it is not only reliable but holds the glue well. Yellow pine also makes a good ground, and, if possible, a board having the medullary rays running through it should be chosen, as boards cut in this way are less likely to twist. All soft woods should be sized before the glue is applied for the veneering process, as otherwise the ground will be

apt to soak up more than its slare of the glue and leave the veneer liable to peel off.

As the tendency of veneer is to pull the ground, making a hollow surface, it is advisable to apply the vencer on the heart side of the wood so that the natural pull of the wood is opposed to that of the veneer. Another good plan, in order to avoid undue twisting, is to damp the back of the ground. Note that wherever possible, the wood should be veneered on both sides.

All grounds should be roughened with a toothing plane before any vencer is applied. This is done after the ground has first been planed perfectly true and llat. After the use of the toothing plane the ground is ready for the veneer, except in the case of a pine or deal ground, when it is necessary first to size it. The size, which is composed of thin glue, is applied hot with a brush and allowed to harden, when it is rubbed down with coarse glass paper and all dust removed with a brush.

Cutting the Veneer. A piece of veneer is now cut to the size required. If knife-cut venecr is used, this operation may be accomplished with a chisel, as in Fig. 1, using a strnight edge to ensure a straight cut. The straight edge should be firmly held down with the left hand as shown and the chisel held in the right with the bevelled side against the straight edge, and drawn across the veneer. The vencer should be placed on a flat board during the cutting to give support for the chisel, and carc should be cxercised at the completion of the cut to avoid tearing away the edge of the vencer. An extra allowance of about $\frac{1}{2}$ in. should be made on all sides.

Saw-cut veneers may be cut with a chisel, if desired, although a better method is to use a vencer saw, as illustrated in Fig 2. The saw consists of a blarle having a slightly rounded cdge and fitted with a handle screwed to one side of the bladc. It is worked against a straight edge, which, if a wide picce of veneer is heing cut, should be hand-screwed or cramped to the bench to avoid its shifting.

For cutting narrow strips of vencer of equal width a cutting gauge may be used. In this case the sheet of veneer is placed to overhang alightly a that board, and another board or a batten sulliciently long to reach the width of the shect placed on the top a short distance from the end and firmly held down with the left hand. The purpose of the top batten is to
prevent the vencer from buckling, whic would render it liable to split. A cutting gauge is then set to the required width and worked along the edge of the sheet in the manner shown in Fig. 3. Only a slight pressure should be maintained, making several light cuts in preference to one decp one. The vencer should not be cut right through from one side, but is reversed after being cut half through and the process then completed from the other.

Veneering. Fig. 3. Cutting narrow strips of veneer wita a cutting gauge. Fig. 4. Heating the glue under the veneer with a flat-iron. Fig. 5. Use of veneering hammer to squeeze glue out beneath veneer. The movement of the hammer is shown in the diagram below. Fig. 6. Cutting overbanging edges away with a chisel. Fig. 7. One-half of veneer laid and remainder being placed in position, edges overlapping. Fig. 8. Cutting through both thicknesses to make a clean joint
Applying Veneer. For the actual process It will be found necessary to reheat the glue of veneering two methods are available, the with the iron once or twice during the process. hammer and the caul. The latter is used for laying saw-cut veneers, and in all cases where built-up patterns of veneers such as quartering and the like are employed. The former method is employed successfully for the majority of knife-cut veneers. Having trued up the ground a flat-iron is heated and glue prepared.

The glue should be as hot as possible, and of such a consistency that when the brush is lifted from the pot the giue runs down in a continuous stream. All the ground is coated with the glue and also the underside of the veneer, care being taken that no grit or foreign matter is allowed to remain in the gluc. The veneer is placed on the ground in position, and the surface rubbed lightly over with the hands. A wet swab is rubbed over the whole to moisten it, and a little glue added so that

Fig. 9
glue underneath is not un duly weakened.
The hot iron is passed lightly across the surface to heat about half the glue, as shown in liig. 4. A venecring hammer is used to remove

Fig. 9. Showing zig-zag movement of veneering hammer illustrated in use in Fig. 5 above. Fig. 10. Details of veneering hammer; it consists of a brass blade fitted into a block of wood with bandle allacked

When the whole has been worked over with the hammer, the surface is wiped clean with the swab and tested to see that the veneer is everywhere down. This may be done by lightly tapping with the finger nails, when if the work is correctly done, a solid fecl is apparent Any bubbles will be obvious from a ho!low sound, and any such places should be remedied by rcheating and working flat with the hammer.

Particular attention must be paid to the edges, which are apt to work up. The overhanging edges are cut away, as shown in Fig. 6, placing the work vencer side downward on a flat board, pressing tightly downward with the left hand and drawing a keen chisel across the vencer. The cross-grain ends should be cut first, since these are the most apt to alway at the ends, the remaining sides being cut after cleaning off any ragged corners. The work is then left to harden, placing it with the veneer side downward. With a very wide board requiring two widths of veneer, one shect should be laid as described and the second shect put down in a similar way. allowing it to overlap the first by about 1 in. Fig. 7 shows the second half being placed in position A straight cdge is placed along the overlapping portion and firmly held in position

while a cut suficiently deep to pass through both thicknesses is made along its length with a chisel, os in Fig 8 The surplus of the upper thickiless is removed and the veneer raised, as shown in Fig 11, so that the surplus of the lower venper may be taken away The vencer is then re. placed heated with the iron, and rubled down with the ham mer Pieces of old newspaper should be glued over the joint to prevent it from openingw hiledrying
Details of a veneering hammer are given in Fig 10 which shows it to consist of a brass blade having a rounded edge fitted into a cut inade in a block of wood, this being fitted with a rounded handle. One method of hold ing it has already been illustrated in Fig 5, using two bands An alternative method is given in Fig 12 in which the hammer is grasped with the right hand only. When the work is quite set, if any bubbles or blisters are seen they should be removed by slitting the veneer with a thin chisel or penknife to let the air out. working a litt!e glue under the veneer and then heating and finally pressing out with the hammer

Cross Banded Work. Fig. 13 shows the treatment of veneered work having a cross banding and an inlaid line at the edges. This is easily aecomplished by first veneering the centre portion as already described except that it is unnecessary to allow the vencer to overlap, rather cutting it slightly sinaller than the actual size of the ground This done, it should be allowed to set

Sieveral strips of cross-grain reneer are then cut with a cutting gauge, as in Fig 3, to slightly more than the width required for the finished banding. One edge of all these should he planed true on a shooting board, a batten being placed on the top of the vencer to prevent it from buckling. An iron plane or linely set trying planc: is used.

The cutting gauge is set to the width required for the banding, including the line, and a cut made on all lour edges of the work deep enough to cut through the vencer, the surplus veneer being removed with a chisel. If any difficulty is experienced in removing it, the glue should be heated with the llat iron, when the veneer will be found to peel off The line is then mitred to fit at the corners and glued round, driving in a few vencer pins at the side of the line if any difficulty is found in keeping it in place. It should be left to harden (Useful bints will be found in the article on $\ln$ laying) The banding is cut to length with

Veneering. Fig. 11. Kassing one piece oi veneer and removing waste alter cotting with chisel Fig. 12. Alternative method of holding bammer, with one land, compare with Fig. 5. Fig. 13. Laying banding, using the back of
ordinary bammer to press out the supcrfluous glue

## in order 10 prevent them opening

The edges of a board or other piece of work are veneered by placing the work in a vice for the purpose This should not be done until the venecr on the top surface is quite set, after
which the ellges should be planed. using a very which the edges should be planed. using a very k :en-edged plane finely set. Strips of veneer are cut and laid by means of the back of a hammer When set they are trimmed off and the surface scraped and glass-papered It is essential to allow all veneered work to set thoroughly before attempting to clenn it up, which is done with a steel scraper, and afterwards finished with glass papier (ste Sicraper)

Use of the Caul. Tolay saw-cut vencers and built-up patterns by means of a caul requires a different procedure. The vencer is firat cut to size and the ground prepared as described for the hammer method, and both then glued. the vencer placed in position and a sheet of paper placed on top In the case of a pattern, two veneer pins should

$\nabla$ eneering. Fig. 14 (above, right). Showing use of cross piece in caul veneering a large surface. Figs. 15 and 16 (below). Two examples of built-up veneer patterns inents are correct.
be driven in to prevent it from shifting. The caul consists of a board about 1 in thick and alightly larger than the ground to be veneered It is slightly rounded in shape on one side. This is thoroughly heated and quickly handscrewed, round side down, on to the veneer on top of the paper the latter being used to prevent the caul from sticking
For a large surface to be caul veneered, cross pieces are used as shown in Fig 14 The upper pieces are rounded on their under edges to force the glue out and the lower pieces -traight and thicker than the top ones, so that when pressure is applied at the ends the top pieces are bent so that their lower edges become straight. It is essential in all cases of caul veneering to work smartly when once the caul has been heated so that the glue is thoroughly melted Other information about the process is given in the article on Marquetry
To vencer patterns such as those given in Figg. 15 and 16, the design is lirst drawn on paper and the various pieces of veneer cut to whape and glued on to the design It is then treated as a whole and laid with a caul For further information reference should be made to the article on Inlaying, where the treatment of simple designs is dealt with in detail

VENETIAN BLIND. Althougl, it has been largely replaced by the ordinary spring blind, which is easier to keep clean and in order, or by casement curtains, the Venctian blind has advantages. It is the British substitute for the continental shutter and has the same useful quality of keeping out the sun and at the same time permitting effective ventilation. Morcover, it permits the gradation of the light, which may be fnlly obscured by having the slats closed or partially by having them slanting. The great drawbacks are the clumsy nppearance of these blinds and the extra cleaning which they entail. Hew people would seleet them for a new house. but where already installed they can be used without trouble for long periods providing the adjust

The blinds should be dusted with a soft brush at frequent intervals, the laths should be

Cross Piece
turned downwith the laths inclined to the window, and the brush stroked from side to side, working from the top to the botiom on the window side first. The laths are then turned in the oppositerlirection and the same procedure followed on the inside of the room.
In the event of broken cords or tapes it is a waste of time to attempt to repair them. New muterial should be fitted, and,
although this can be done with the blind in position, it is usually more convenient to take it down, and at the samie time to lonk over the other adjustments. The top lath of the blind is either screwed dinectly to the window framing with two screws or supported on small metal bracketa, the latter being the more satisfactory. In old fittings the screws become loose and fail to hold the blind up. The remedy is to use screws of a larger diameter, to plug up the old holea with a glucd peg, and to rehang the b!ind with two small iron angle brackets.
To remove the blind either for thorough cleaning or repair, it should he let down, the tapes unfastened at the bottom, and the cord unknotted and withdrawn. The laths are now slipped out and the top screws removed. With a bracket fastening the blind will remain in place after the screws are removed, hut with those fastencd direct to the window frame each screw should be undone for a few turns, so as to equalise the atrain and allow the top bearer board to be held in position while the screws are entirely withdrawn. The blind is laid on the lloor and the tapcs gathered up close to the laths, so that the blind can be carricd away.
If possible the shop practice of supporting the hlind on angle brackets should be adopted. The brackets can be attached to the wall, to an old door, or to a temporary framework erected for the convenience of handling. If this method is not possible the blind should be spread out at full length on a large table or on the floor. The tacks securing the tapes to the bottom lath should be pulled out with a pair of pincers, the tops of the tapes taken off in the same way, and the lengths can be washed if they are in good condition.
To clean the laths, they should be gathered together and placed in a bucket of sonpy water. so that this edges can be rubbed over with a scrubbing brush. Each lath should be scrubhed over on both sides, and then rinsed in clean water, and placed on one side to dry. The laths should be rubhed over with a dry cloth, and then with beeswax and turpentine, the final polish being given with a soft clean duster.

In some casea a better appearance can be given to Venetian blinds by painting them cream colour or almond green. All blinds in front of a house should be of the same colour. The old paint must be removed and the surface of the laths smoothed with glass paper and given a coat of weak glue size, before applying the necessary coats of paint. Paint with a very hard glossy surface, suitable for exterior work should be chosen for the purpose, otherwise with exposure to the sun there will be a tendency to blistcr.
Re-taping the Blinds. The work of retaping and recording can now be proceeded with. The tape, known as ladder tape, is obtained in several qualities; the best has the ladder or connecting pieces woven in with the webbing, as in Fig. 1, and no other kind should be used. It is mads in unbleached, half-bleached, and white, as well as in green huff. and red. In addition to the lengths required for the laths, two or three short lengths are needed to attach the top lath to 1.he bearer, and these are known as the shading tapes. The total lengths of the now tape and cord after being carefully measured can be secured to the laths with tintacks.

The shading tapes are supported on rollers, which are provided with $n$ long spindle, and fit in slots cut in the top of the bearer. They are not, as a rule, liable to damage, but they should have free movement, and be fixed so as to be parallel with the surface of the bearer. Each length of webbing, which can be taken from the ladiler tape by cutting off the cross pieces, should be 10 in., threaded through the roller opening, carried over the roller, and
brought out to the same side. The ends are folded under and tacked to the top lath, as in Fig. 2, resting the lath on a block of wood so that the tacks can be driven in tightly. In blinds where there are three shading tapes, the two end ones should be secured tirst, taking great care that the top lath and the hearer are quite parallel, and that the lath just clears the bearer when turned up.

The centre tape is adjusted to support the lath and prevent sagging. The long ladder tapes are secured to the top lath, so that the centre is exactly underneath the pulley wheel opening (Fig. 3) $\mathfrak{y}$ about $\frac{3}{} \mathrm{in}$. of the material being turned in undernenth to hold the nails. The ladders must be the same height each side to ensure that the laths will be horizontal, and it is an advantage to hang the blinds on temporary brackets and to fit a couple of laths in position. The double cord for the shading adjustment is secured to the top lath by nailing it in a narrow groove provided for the purpose. Before the cord is fastened on, a Venetian driving cye should be threaded on.

The laths are slipped in position while the bearer board is suspended on the brackets, and the new cord can be threaded through each lath, taking care that the cord runs between the alternate cross pieces of the webbing. Sufficient length of cord should be allowed to bring the loon
should be tested, and it correct the ends of the tape should be folded underneath and secured with two or threc tacks.
In the event of a lath being broken, a new one can be made from a picce of yellow pine planed to the required width and thickness and cut to length. The holes should first be hored with a sinall centre bit and enlarged with a fairly flat scribing gouge: the blind maker would punch the hole out, but this is rather a risky procecding for the amateur There is no nced to take the blind down to fit a new cord. It is a simple matter to thread the cord through the holes and over the pulleys in a bracket-hung blind: in a screw-hung blind the screws can usually be undone sufficiently to allow of enough space to slip the cords over the pulleys.

Old blinds sometimes cause trouble through the cord slipping off the pulleys, causcd by the edges of the pulley being broken or by the opening of the slot being too large. The remedy in the first case is to fit new pulleys; they are generally held in place by a pin, which can be withdrawn with a pair of pliers. A new pulley wheel can be fitted in and the pin replaced. In the second case, the best method is to attach thin strips of wood, to provide a guide for the cord. Another method is to drive a staple as close as possible to the pulley so that the position of the cord is always over the pulley no matter how slack the cord is.

VENETIAN GLASS. This phrase is applied primarily to glass made in or near Venice, but also to pieces made in the samc style by workmen in other countries. The Venctians discovered the way of making the type of glass since linked with their name in the 13 th centurv, but their furnaces were on

Venetian Blind. Fig. 1. Webbing or tape with ladder pieces woven in. Fig. 2.
Method of securing shading tape to bearer. Fig. 3. Blind complete with new Method of securing shading tape to bearer. Fig. 3. Blind complete with new tapes and cords, showing laths in position
the island of Murano, being regarded as too dangerous to be in the city itself. The industry flourished until the 18 th century, partly owing to the jealous care with which its secrets were guarded. It then fell into decay, but was revived in the 19th century.
The characteristics of Venetian glass are its extreme lightness as regards weight and a slight cloudiness of within easy reach when the blind is fully down. hue. The general features of the simpler This is adjusted by securing one end by drinking glasses are a very open bowl, a high, means of a knot, which should fit in the often almost conical, foot, with a folded edge enlarged hole in the underside of the bottom lath, and then pulling the other end through the hole until sufficient remains on the outside. The spare cord is cut off, the end knotted and pulled in to the hole.

With large blinds and those screwed to the window frame, the cord should be threaded through the pulleys and tied while the bearer lath is secured. When the cord has been threaded and secured at the bottom the blind
often almost conical, foot, with a folded edge and a stem slight in proportion to the bowl. In the design there is a sense of poise and balance. Engraved clecoration is rare, but enamelling and gilding adorn the earlier pieces, which sometimes have diamond-scratched designs.
Early pieces, being extremely valuable, are rarely seen in private collections. The glasses of the 15th century, as they were modelled on silver cups of the Gothic style, have a somewhat heavy appearance, but in the 16th
century more delicate picces were made, and sonc of the finest existing examples date from that time. In that period the glass hecame thinner and lighter, relying less and less on enamelling for its beauty. The tiligree was claborated and difirrent colours were employed. Pieces were also made in the form of lions, dragons, gondolas, ctc. The mascaron (q.v.) or raised ornament of glass was often used on vases and bowle. See Glass Ware.
VENISON : How to Cook. Before it is fit for the table venison requires to be hung for two or, if the weather is cold, three wecks.
The principal joints are the haunch, which includes both the loin and the lag, the shoulder, the neck and the hreast. Of thesc the favourite is the haunch, which is roasted and served with rich brown gravy, accompanied by either red currant or rowan jelly. The meat for the greater part of the time it is roasting should be covered with buttered paper placed over a llour and water paste, in order to keep in all the juices and retain the flavour.

To roast haunch of venison, saw off the shank bone, also trim the chine and pare away darkened skin and sinews. It is often necessary to remove entirely the outer skin of venison before roasting it, especially if well hung. Butter a large sheet of kitchen papur and place two more shects underneath it. Cover the meat with a stiff llour and water paste, roll in the greased paper and place it with sufficient butter or good beef dripping in a baking pan and roast it in the oven from $2 \frac{1}{2}$ to $3 \frac{1}{2}$ hours.

It must cook gently ofter the first 15 min ., and must be well basted several times during the process of cooking. About 12 min . before the haunch is ready, remove the paper and paste, scason the meat with salt and pepper, dredge it with flour, baste it and expose it to sharper heat to give it a brown tint. When well frothed up and a rich but not very deep brown, dish it up and serve it very hot, with a superior thick gravy, in a tureen.

The gravy is made as follows: Chop smali the knuckle boue and trimmings off the chine and fry these, with any game or chicken hones left over, in "? oz. butter, adding 4 prepared and chopped shallots, a bouquet garni, and a shredeled stick of celery. Fry all until a pale brown, then add seasoning and 1 gill white wine. Simmer these until ther are reduced to " gla\%e, stiring all the time that the liquor is reducing. Then add $\frac{1}{2}$ pint good stock, mix it in well, and cook very gently for 25 min . The essence is now skimmed and strained through a fine hair sicve. Have ready heated in a saucepan 1 pint good brown sauce and mix in with it the game essence, also the strained juice of half a lemon. lboil all up together and pour the gravy into a turcen.

Venison Pasty For an old-fashioned pasty, bone the shoulder, but as it is sinewy beat it well and steep it in vinegar to which" 2 glasses port wine have been added, leaving it in this pickle for 24 hours. It is better to rub the joint well with sugar before putting it into the vinegar. Do this for 2 or 3 days. When required for use, be careful that al! iraces of suga: are cleared away and that the joint is wiped quite dry from the wine and vinegar. Season it with salt and pepper, then lay the toned shoulder in a large earthenware dish.
Melt $\frac{\mathrm{lb}}{\mathrm{lb}}$ hutter and pour it over the meat, adding $\frac{1}{2} \mathrm{lb}$. fat from a loin of mutton cut fine. Sprink!e over it a little grated nutmeg, clove or mace, and 12 shallots which have heen peeled and chopped Half fill the dish with good stock, and cover it with a light pastry as for meat pie. Bake the pastry sharply for about 90 min ., then slowly for from 31 to 4 hours. The crust must be very rich or it will dry in the long baking.
To make a more modern dish use about 2 lb . of a boned shoulder of venison, beat and

Venetian Glass. Turee beautiful specimens oi whice Yenetian glass, tuat on the right having a stem enclosing orange flowers in coloured glass

5 min., or until well coloured. Put them with the meat and gravy into a stewing jar, add 24 button mushrooms, and cook all gently in the oven or on the top of the stove, drawn back from the fire, for about 2 hours or until the venison is tender.
When ready to serve, remove the bouquet garni, clear the gravy from fat and scum and dish neatly gar nished with croûtes of fricd bread. Mushrooms suitable for this dish may be procured preserved in bottles, and if button onions are not obtainable a Spanish onion peeled and cut into neat pieces may be used in place of them.
Casserole of Venison. For a stewed loin of venison, trim the loin and cover the fillet soak it, and prepare as for the pasty, but cut portion underneath with thin slices of bacon. it into neat pieces. Lay these in a pic-dish and season well, also dredge them with flour Arange among the picees 12 small rolls of bacon and the same number of forcemeat balls, then fill up with good atrong stock into which a wineglass of port wine should be introduced The pie must he covered with a rich rough puff pastry, and will take a bout 2 hours to bake. It should be ornamented and glazed. After it is cooked the centre ormament should tee removed, and in the vent should be poured as much extra gravy as the dish will hold. Venison dishes must always be served very hot. French beans are a good accompaniment.
Jugged Venison. For this savoury dish bone the shoukler and cut the flesh into neat square picces, lut first prepare the meat by beating it and soaking it. Fry the venison with 3 lb. bacon cut in dice until it. is a good brown, then drain off all superlluous fat. Dredge over the meat 3 oz. llour and fry again a fow minutes in order to cook and colour the llour. Keep a! moving, and be careful that the flour does not burn. Now moisten the contents of the pan with 21 pints good brown stock and $\frac{1}{2}$ pint port wine Season well, and add a bouquet garni.

Stir frequently till the whole comes to a boil, and then simmer while preparing the following flavouring: Procure 24 small button onions, peel them and fry them in butter for about
portion underneath with thin slices of bacon.
Tie or skewer these in position, then place the joint in a large casserole with a prepared and sliced carrot, 2 onions, also sliced, a bouquet garni, a lump of butter as large as a hen's egg, $40 \%$ bacon rashers trimmed and cut into strips, 4 cloves, and seasoning. Put the lid on the casserole and let all cook together.

After it has cooked for an hour add 1 pint stock and continue cooking for at least another hour, still turning and basting occasionally Jish the ineat. removing the string or skcwers, and keep it hot. Strain the liquor in which it has been cooked and free it from fat. Add 3 gills brown sauce, a small pot of red currant jelly, a wincglass of port wine, and scasoning to taste. Pour the gravy round the meat and garnish with potalo eroquettes.

The renıains of a cooked joint of venison may be hashed. Place a sliced onion in $\}$ pt. stock, season, add 1 tablespoonful red currant jelly and hoil for a few ninutes. Dust ncat slices of venison with llour, ardd to the stock, etc., and remove the onion. Stew a few prunes with lemon-juice to taste. When the venison is heated, place it round the prunes on a hot dish and garnish with sippets of toast.

The fry of venison makes a good breakfast dish Wash and soak the fry well, then cut into neat pieces and roll each in seasoned Hour. Fry them in butter and dish on fried parsley. Fry them in butter and dish on fried
See Casserole ; Firy ; Rowan ; S auce.

## The Ventilation of the Home

## Modern Ideas on a Matter of Vital Importance

This subject may te pursued further in this work under such entries as Architecture; Chimney; He ting; House ; Window. See also Air-Brick; Bathroom ; Geyser

Incfficient ventilation is often a contribu- per hour for each 1,000 cubic feet of space. tory cause of ill-health. Unless a room is The carbonic acid content of the air is im supplied with ventilators, or the windows are kept open, sufficient fresh air cannot enter. An outlet for impure air is as necessary as an inlet for pure air. Therefore, if there is no chiminey, an opening must be made in the wall.

The air of a room becomes impure mainly through the breathing out of the occupants and the carbonic acid gas produced by burning gas lights or oil lamps. Besides carbonic acid, the expired air contains organic matter and watery vapour. A man sitting in a room will breathe out 6 of a cubic foot of carbonic acid gas in an hour. To keep it at a wholesome degree of purity. from 2,000 to 3,000 cubie feet of air should be introduced
portant as an index of the freshness of the air, and thercfore of the efliciency of ventilation. or, in other words, of the movement of air within the room The malaise, or sense of illness, which is a consequence of a stuffy atmosphere has been shown to be due to stag. nation of air round the bodies of the occupants.
The general result of such stagnation is $\Omega$ diminution or suppression of perspiration, which function is always going on, although we may be unconscious of it. The regulation of body temperature is thus interfered with. Equally important is the loss of stimulation of the nerves of the skin, caused normally by the circulation of the air about the skin. The
effect of this stimulation is to produce an exhilarating sensc of well-being
It has been found that average air in town arens contains nbout 4 parts per 10,000 of carbonic acid gas; the air of a room ought not to contain more than 6 parts. Closely related with this matter is the size of the room A bedroom for one person should be of at least 800 and preferably 1,000 cubic feet. In calculating the cubic capacity of a room the length, breadth, and height are multiplied together, but any height above 12 ft . is not to be counted, because nliove that level little change occurs in the air. The floor space is also important, and for that is suggested $1_{12}^{2}$ of the cubic space
In the climate of Great Britain it is found that the air cannot ordinarily be changed oftener than three times in an hour without the process causing a draught, so that to sccure a supply of 3,000 cubic feet of fresh air per hour the room sjace must be 1,000 cubic feet. A certain degree of draughtiness does not matter so much in a bedroom. A good airing of a bedroom in the daytime is not sufficient. and ventilation during the night also must be provided for It is usually best to keep a window widely open; there is less draught than when only a small slit is left for the air to enter, as the amaller the opening the greater will be the velocity of the air current. If the bed is not between the window and the fireplace no harm results, as a rule, from the wind blowing through the window on to the slecper. But if he is liable to neuralgia or toothache he may have to avoid this. With a screen properly placed, full protection can be obtained from draughts.

Using a Sash Board. For ventilating a room a good plan is to raise the lower sash 4 to 6 in and fill up the open space with a 1 in. thick

Ventilation. Fig. 1. Ventilator consisting of a movable piece of perforated glass fixed to a window pane with similar perforations
board plared between the sash beads. The lower sash is shut down on to the board, which can be painted to match the window frame. This arrangement allows air to conce in between the lower and upper sashes, and as it is directed upward there is no appreciable draught This is called natural ventilation Some artificial system may be necessary for sitting-rooms, nnd may be applied to sleeping rooms as well. There are many such systems. In some houses one secs a small grating fixed near the ceiling to draw away the hot air. It may be arranged that the air passes into the chimney, a backward current being prevented by a valve

A good appliance is the Sheringham vulve, in which there is a wedge-shaper projertion let into the wall of the room, communicating with the outer air and directing the current
of air upward. This ventilator should be an oillamp in the grate, or to light a gas placed about 5 or 6 ft . from the foor. Another jet in the chimney when no fire is going is the Tobin tube. This consists of a shaft This is essential in a sick-room. It must be leading up the inside of the wall to a distance of 5 or 6 ft . The lower end cominunicates with the outer air through an opening in the vall, guarded by a grating. Valves are attached to regulate the amount of air admitted. A screen may be placed in the shaft to filter the air from dust, or a coil of hot-water piping to warm the incoming air

Perforated bricks in the wall also serve to ventilate a room. The openings through these are wider on the inside so as to diminish the force with which air enters. Air movement can be brought about by an electric fan, and if this is placed so that it can direct an air stream in a suitable manner, i.e. towards an outlet, the air is not merely agitated, but exchanged.
The Cooper ventilator Fig. 1) consists of a piece of g!ass which is perforated with four or live holes of a bout $1 \frac{1}{2}$ in. diameter. The perforation is covered with a clisk of glass having per. forations to correspond with those in the other piece of glass The disk moves on an vory pivot which passes through glass and the disk; a stop is also arranged so that the disk will not revolve beyond a certain point, that is, either open or closed To open the ventilator the disk is turned until the holes of the glass disk and the glass sheet coincide.

With the Boyle type of ventilating radiator fresh air is admitted by adjustable air inlets in the wal!, and passes through a radiator heated to a suitable temperature, thus proviling heat as well as ventilation This method has the advantage that two objects are served by one piece of apparatus, and there are no objectionable littings beyond the radiator.

A very simple outlet can be provided by inserting in the external wall a Boyle's mica llap valve. This consists of a metal box having n grid in the front; the inside has a smooth seating on to which fits a piece of mica sus. pended from the top of the grid. The expired air lifts the mica flap and passes outwa:d. The action cannot be reversed, because any air which attempts to pass through from the outside pushes the mica Hap on to its seating. liy the use of this appliance good ventilation can be arranged for bed rooms or apper uoms.
The Boyle air inet panel shown in: Fig 2 is adjustable by opening or closing the Hap at the front, which when open directs the contering air in an upward path so that the fullest advantages are oblained from its use.
When a fire is burning and the window is open there is a good How of air, but if there is no fire the outward current may be very slight. It is a good plan. there fore, if a room lends to get stuffy, to burn remembered that gas and oil lamps vitiate the air of a room to a considerable extent bil against this may be set the fact that air currents are caused, which cffect an exchange if suitable inlet and outlets exist Even when a room is large the air will be impure unless there is free and constan circulation and renewal.

Under-floor Ventilation. The ventiation of the space above the ground and beneath

Fig. 2. Boyle air inlet panel
the floor of a house is pro vided for by building air bricks or gratings into the outer walls just below the damp coursc The sleeper walls, too on which the joists are supported, are built up in honeycomb fashion, so as to leave a number of interstices through which air can cir culate. Unless the under foor space is well ventilated the timbers and floor boards are prone to the attack of dry rot (q.v.) it is im. portant-though trequently neglected - to ensure that the ventilating bricks or gratings should not be obstructed on the outside by earth, plants, etc.

VENTILATION : For Plants. In the greenhouse ventilation is of supreme impor tance, for whilst the glass will rapidly conserve and bottle up sunshine, it will not readily allow the accumulated heat to escape. Too much fresh air cannot be given from the middle of May to the middle of Scptember. During April and the early days of May more care is necessary, owing to weather vagaries.

In winter, ventilation should be allowed whenever the air is mild, opening up during mid-morning and always closing down between 2 and 3 p.in. When the air is very dry or very cold, ventilation should be reduced to a mini mum, and unless heat is available to give it warmth before entrance, top ventilators should be opencd in preference to those at the sides. Another point to remember is that ventilators must be opened to lecward and closed when the wind direction changes. During spells of very severe weather ventilation must be restricted to an hour, or even less. It is a safe rule to open top ventilators lirst, following, when neecssary, with the lower ones, but always

Ventilation: fer plants. 1. Greenhouse ventilation: $a$, lights; $b$, pipes arrows dennte direction of air currents. 2. Frame ventilation: $a$, bricks; b, ligat block. 3. Cloche ventilation. 4. Ventilatinn of a forcing house : $a$, fies ; $b$, pipes ; $c$, lights ; arrows denote air circulation
opening them on the same side of the housc. dVhen constructed ol timber and glass after the Sliding lights are now out of date, and in manner of a conscrvatory, as shown bere in oul modern houses the runs of ventilators are illustration of a first lloor verandah, it forms levered open to any desired aperture at one time, separate levers controlling top and bottom. Another important detail is provision of holes in the brickwork to admit air, where it will be forced to pass around the hot water pipes as showI in the diagram; this arrangement is usially adapted to large bouscs, but it may very well he arranged in those of smaller type. Ventilation of garden frames is often neccssary. and our sketches show simple and effectual methods.

VENUS FLY TRAP. The plant to which this name 18 given is a greenhouse herhaceous perenninl with white Howers. The leaves are edged with sensitive teeth, which are said to close up and interlock when a Hy or other insect alights upon them. As soon as the insect is doad the leal reopens. The plant, popular only as a curiusity and for collections, is grown in equal parts of peat and sphagnum moss.

VENUS' LOOKING GLASS. The hest known species of this hardy annual flowering plant is Specularia speculum, which grows 1 ft . high, with oblong or lance-shaprd leaves, and purple Howers in July. It will thrive in any fairly good garden soil in a aunny bed or border.

VENUS'S NAVELWORT. This name describes a small group of low-growing plants suitable for the rock garden. One of them: Omphalodea linifolia, is a pretty hardy annual, 10 in . high, with white flowers in late spring or summer from seeds sown out of doors in autumn and spring respectively. It necds rather light soil and partial shade. Of the perennial kinds the best are cappadocica, verna, and Luciliae.

VERANDAH. In its usual form a verandah is a raised covered-in extension from an outside wall of the house. In some styles of architecture it is a special feature of the building. A certain type of Victorian villas, for instance, have long narrow vernndahs, situated a few steps above the ground level. The chief draw back to this style is that it darkens the rooms opening on to the verandah, with its curved iron roof, trellis, pillars and railing all obscuring the light; also it is not wide enough to nflord the compensation of being a useful open air sitting-room.

In more recently huilt houses of corresponding size the comparatively apacious bricked, tiled or paved loggia lias largely supplanted the old-fashioned verandah. The latter, however, in a wider form is a convenient extension over a porch or in conjunction with a large balcony on an upper floor.

Verandab. Constructed of timber and glass, this firat floor verandab with its comfortable furnishing forms a pleasant sun parlour

Humphrev \& Vera Joel
a sun parlour. Sectious of its glazed front wall are movable and the glass roof doos not darlien the adjoining living-room. See Conservatory Garden Furniture; Glass: Loggia.

VERATRUM. This is a vigorous hardy herbaceous perennial plant with large leaves and Hower spikes which reach to a boight of 3 ft . to $\mathbf{4} \mathrm{ft}$. It is suitable chicfly for the wild garden or large herbaccous border. It llourishes in ordinary well-tilled and manured soil The chief kinds are album, 3 ft ., grcenish; nigrum, 3 ft., dark maroon; and viride, 4 ft., greenish : all hloom in summer. The rootstocks have poisonous properties and hell. bore powder, used as an insecticide is mnde from the roots of Veratrum viride and album.

Verbascum. This is an alternative name for the border plants known as mullein (q.v.).

VERBENA. This is the name of a popular half-hardy plant which is largely grown for use in summer Hower beds. There are several named varieties, of which the prettiest is the pink one named Miss Willmott, but a packet of mixed seeds will provide Howers of brilliant and varied colouring. If these are sown in a heated greenhouse in Jan. or carly Feb. the plants will bloom in summer. They must he grown in a compost of loan, leaf-mould and sand and gradually hardened off for planting out in June. Cuttings may be taken in August and inserted in pots of sandy soil in a frame.
Verhenas makc charming summer llower beds and yield a wealth of bloom if the shoots are prgged down. Verbena venosn hicars lilacpurple Howers Verlsena chamaedrifolia, which is suitable for the rock garden or a sunny horder of light soil, has scarlet blooms.

VERDIGRIS. This is a green or greenish blue subatance formed by the action of an acid on copper and on metal alloys containing copper. It is used as a stain and a dyc, and for this purpose is produced by subjecting copper to the action of acetic acid.

Articles made of brass are liable to the formation of verdigris, which can be removed by dipping in a strong potash solution. Hydrochloric acid in a weak solution can be used for removing verdigris from articles of rolled gold, and, unless plated articles are badly coated, when the aloove method can be used it will he sufficient to wash them in strong soda water. Sub-acetate of copper or verdigris can be cmployed as a green stain by dissolving it in a hot solution of vinegar. It is also employed in making an ebony atain. See Brass; Bronze; Bronzing.

## VERGE. In gar

 dening operations the straight or curved edge of a lawn is known as the verge. It has to be kept clean and true after the mower has cut the grass as near to the boundary as possible. An edging iron is the best implement to cmploy, aided by a garden line stretched from end to end of lawn.There is also a machine called a verge cutter, which trims off all projections of lawn edges. This cutter is sup. plemented by a knife blade, which requires frequent sharpening. See Lawn.

Verbena. Flowers of the pink parlety, miss Willmott
VERMICELLI: Cookery Uses. A deli cate Italian paste, vermicelli is so called hecause of its thread or wormlike a ppearance. It is used for puddings, sweets and savouries soups are thickened with it, and it forms an excellent substitute for breadcrumbs in the coating of emall cases.

All Italian pastes differ in the time required for cooking them, as if the paste is old or stale it takes longer to soften. Good fresh vermicelli should be done in from 5 to 7 min ., and on that account is valuable when time is limited. No Italian paste should be soaked before it is cooked, but just dropped into plenty of salted boiling water, stirred occasionally, and drained off as soon as it is done.

For thickening clear soup, boil the vermicelli as directed above. Have the soup ready flavoured and strained, put the vermicelli into the turcen, and pour the soup, boiling, over it. Use 2 to 3 oz . paste to each quart of stock. For a family soup the vermicelli may be sprinkled into the hoiling soup about 10 min . before serving it and stirred till it is soft. This latter method saves the use of extra utensils.
The following is a simple but nourishing dish for children: Put into 1 pint boiling white broth or milk 2 oz . rermicelli, season and flavour to taste, and then boil for 5 min ., striring all the time. This should be served with rusks.

Vermicelli Sweets. Vermicelli pudding is steamed, and will take 1 pint milk, the rind of a lemon, 2 oz. castor sugar, 4 oz . vermicelli, and 3 cggs. Infuse the rind of the lemon in the milk for 40 min ., adding a pinch of salt, but be careful not to let the milk waste. Then strain out the lemon and return the milk to the saucepan used for the infusion. Bring it to the boil, and stir in the vermicelli (cooked). Continue stirring over the lire for 4 min ., then draw the pan back. Beat the eggs and sugar together, and mix them thoroughly with the milk and vermicelli. Turn into a greased basin and stcam $1 f$ hours.

A tritle may be made in this way: Cook 6 oz. vermicelli in salted water and drain it. Have rearly $1 \frac{1}{4}$ pints rich custard. Melt $\frac{3}{4} \mathrm{oz}$. gelatine in 2 tallespoonfuls of water, mix this with the custard, and pour both over the vermicelli. Set the misture in a border mould or in a diah, the centre of which has been filled in with a smaller dish. When firm, turn it out and
arrauge it in a glass dish. In the middle of the removed to a cleansing station, the court, if border place a layer of sponge fingers and ratafias soaked with sherry. Cover them with red chopped jelly, and heap it in a mound. Then pipe the whole with Havoured and sweetened whipped cream. Finish by decorating with coloured sugars.
Vermicelli Pie. An excellent pie is made with 4 oz . cooker vermicelli, \& lb . cold meat minced (chicken or veal for preference), 3 or 4 lomatocs, a little grated nutmeg, seasoning, $\frac{1}{2}$ pint vegntable flavoured stock, 4 o7. grated cheese and breadcrumbs. Arrange all these ingredients in layers in a greased fireproof dish, reserving sufficient breaderumbs to cover the top, on which place small dabs of butter, and bake about 20 min . in the oven.

VERMIN. In English law this word is delined to include bugs, Heas, lice, itch, mites and their eggs, larvae and pupre The Housing Act, 1925, states that for houses of a certain rental there is an implied condition that the house is at the commencement of the tenancy in all respects reasonably fit for human habitation, and a similar condition is to be found in the Rent Restriction Acts. Therefore if a tenant moves into a house and directly afterwards finds that the house is infested with vermin, he or she has just cause for complaint against the landlord; damages have been awarded in the courts in such cases.

Many large towns, including London, have acquired powers to deal with vermin, verminous rooms and persons by means of local acts; others have adopted the particular sections of the Public Health Act, 1925. dealing specifically with vermin, and action can be taken under this Act against the persons who cause the vermin. Again, all local authorities have powers given them under the Public Health Acts. 1875 and 1891, to deal with premises which are a nuisance, and injurious or dangerous to health. Several towns have obtained powers by local Acts to deal with the dirty tenant, and where it is proved to the satisfaction of the court that within twelve months of a room having been properly cleansed they have by neglect and filthy habits made the room verminous a fine may be iniposed.

London has considered this subject fullyat various times, and borough councils have the right to enter premises, inspect and serve notices in writing upon the owner or occupier of a house or room to have it cleansed within a certain time, and if necessary to remove necessary to remove showing a measureme
the paper from the walls for the purpose of destroying and removing the vermin. Failure to do so niay upon conviction cause a fine of 10 s . may do the work and recover the costs.
The practical working of this is as follows : A complaint is lodged, or it comes to the knowledge of the sanitary authority, that a housc or room is verminous. The sanitary inspector visits and possibly finds the tenant has only bern there a short time, obviously then the liability is the landiord's and a notice is served upon him to remedy same. However, if it is found that the tenant has occupied the room for some time and the vermin is caused by his or her cirty habits, then the liability is theirs. Much trouble is caused by people huying old furniture and clothes and inporting them into their rooms.

A new departure in public health law which applies to London only came into force in 1928. On the report of the medical ollicer of health that a person and clothing is infeated with vermin. and such person will not consent to be
removed to a cleansing station, the court,
satistied with the application of the local authority, may order his removal and detention. The local authority may take such measures as necessary to free him and his clothing from vermin. Females are protected, inasmuch as the examination of such must be carried out by a woman or a doctor. No charge is made for this personal cleansing.
The Children's Act, 1908, gives the school medical officer and nurse power to examine children, and if it is found that such children are infested with vermin or in a foul or filthy condition, the local authority can give the parents or guardians of such child a notice in writing requiring them to cleanse properly the person and clothing of the child within 24 hours of the receipt of the notice. Failure to do so gives the officers power to remove the child and detain him or her till they are satisfied that the child is properly cleansed.
VERMOUTH. The mild cordial known as vermouth is marle from white wine ilavoured with wormwood and certain vegetable extracts. It is used mainly as an aperitif before luncheon and dinner and as an ingredient in several cocktails. A favourite appetizer is a French and Italian vermouth mixerl half and half.

A vermouth cocktail is made with two dashes of Angostura bitters and one portion of Italian vermouth, filled with ice, mixed and strained into a cocktail glass. Another cocktail is made with three dashes each of Maraschino and Angostura bitters. Add one portion of Italian vermouth, fill with icc, mix and strain into a glass, the rim of which has been moistencd with lemon peel and then dipped into some powdered sugar. See Cockitail.

VERNIER: On Calipers. This is a device applied to a scale to give accurate readings in fractions of the smallest division of the scale. It is used on micrometers, caliper gauges, and scientitic instruments that are designed to work very exactly.

A sliding caliper vernier is shown in the accompanying illustration, as engraved on the sliding jaw. The scale on the shaft gives mcasurements in tenths of inches. The vernier scale has ten divisions, together equal to nine divisions of the scale; each therefore representing ${ }^{8} 0$ of $\frac{1}{10}$ of an inch. In the illustration the zero mark of the vernier has passed the inch mark of the scale, but has not reached the next I' 0 inch mark. To decide the value of the fraction the vernier is consulted, and its 7 line is found to correspond exactly with a scalc mark. The 6 line of the vernicr is $\frac{1}{10}$
of $I^{2} 0$
inch to the right of the nearest scale mark on its left; the 5 line, $\frac{1}{2}^{2} \sigma$ of ${ }^{2} \sigma$ inch: and so on to the zero mark, which is $\frac{7_{1}^{7}}{7}$ of ${ }_{10}^{10}$ inch beyond one inch. The reading thercfore is 1.07 inch. A finer reading could be made if the vernier scale had 20 divisions equal to 19 of the scale, as the difference would then only be $\frac{1}{20}$ of $I^{\prime} \delta$ inch.

The vernier incorporated in a micrometer gauge is essentially similar in principle, though the scale is engraved around the thimble of the gauge. See Gauge ; Micrometer.

VERNIS MARTIN. A brilliant lacquer or varnish used in the painted decoration of articles such as fans, fancy tables, and cabinct panels, takes its name from a French family who during the 18th century developed a form of artistic decoration based on oriental lacquer work. See Lacquer; Watch.
Veronica. Hardy and half-harly evergreen flowering shrubs and perennial plants popularly known as speedivell (q.v.).

VERTEBRA. The spinal column is composed of a large number of separate bones superimposed one on the other, the object of such an arrangement being, of course, to secure Hexibility. Typically, a vertebra consists of a mass of bone in front, the body. and a bony arch behind. The first ccrvical or neck vertelira, known as the atlas, the one on which the skull rests, does not possess a hody, but consists simply of a ring of bone. The next one has on the upper surface of the body a long tooth-like process which engages in the front part of the ring of the atlas. The object is to permit of rotation of the head.
The bodies of the vertebrac are separated from each other by disks consisting of fibres and gristlc. Thesc, known as the intervertebral disks, increase the clasticity of the spine. The arches placed one over the other and the broad ligaments connecting the vertebrae form the spinal canal, which contains the spinal cord. The five sacral vertebrae are

Vetch. Dainty rose-pink flower clusters and vetchlike leaves ol Coronilla varia
fused to cach other in adult life, forming a single bonc, and the same is true of the four coccygeal or tall vertebrac. See Spine.

Vertigo. See Dizziness.
VETCH. Plants with small pea-shaped flowers, vetches are of little decorative valuc. Vicia fulgens, of slender climbing growth, has red flowers in summer. Vicia faha is the broad bean. Coronilla varia, 2 ft . high, has vetchlike leaves and rose-pink blooms.
VIBURNUM. This is a family of beantiful hardy Howering shrubs, with white Howers. Most of the species are deciduous, or summerleafing, while some are evergreen. See Guelder Rose ; Snowball Trec.

VICE: Different Types. The principal requirements in a vice are strength, rigidity, and a tight grip. Vices are made of many patterns, each specially suitable for some particular class of work, but the type in Fig. 1 is the most useful when a single tool has to be depencled on for jobs of all kinds.

One jaw is fixed while the other is movel in or out as required by a screw mechanism concealed in the body of the vicc. The screw is turned by a tommy bar which can slide through a hole in the projecting head of the screw, and has knobs on its ends to prevent it from dropping out. In addition there is a spring catch at the side, a touch on which frees the screw mechanism so that the vice can be open or closed rapidly by hand, the screw mechanism being then used for the final closing of the jaws tight on the job.

The jaws of a vice are serrated and hardened in order to provide a good non-slipping grip; and therefore some protection is needed when
 very rigid, as any movement, however slight, is most objectionable. especially when filing. If the available bench proves to be unsteady, it can generally be inpproved by screwing wooden thattens, say, 2 in. by 1 in., diagonally from the bottom of one leg to the top of the second all round the bench and screwing the legs to the floor with angle hrackets.

In choosing a vice the first consideration is the purpose for which it will chictly be required. If heavy work is to be done, such as forging or smith's work, then one of the regular hlacksmith's leg vices is essential, but for the repair of a car or for bending heavy metal the regulation engineer's vice shown in Fig. 1 should be chosen. The width of the jains shoulal preferably be about $3 \frac{1}{2}$ in., and the opening up to about 6 or 7 in. This class of vice mist be securely bolted to a strong and rigid bench. For lighter work, a vice of the pattern illustrated in Fig. 2 is suitable. It is made of cast iron from $1 \frac{1}{2}$ to 3 in . wide, and is not, as a rule, provided with quick release mechanism. It is serewed to the top of the work bench with stout wood screws.

For occasional use, the portable bench vice in Fig. 3 has many advantages, chief of which is the provision of a self-contained clamp with clamping screw which enables the vice to be attached to the worl bench, kitchen table, or other convenient means of support. If the vice is ta be used for any length of time, a couple of wood screws can be inserted in addition to prevent it shifting.

Woodworker's Vice. For woodworking, a joiner's or carpenter's vice, as shown in Fig. 4, is usually most serviceable. It is made in several sizes, usually with a quick relense mechanism. This comprises a small trigger, located near the screw handle, the action being to press the trigger and pull the vicejaw in or out to its approximate position, then release the trigger and tighten up the vice in the usual way.

These vices have smooth faces to the jaws, and can often be used with wooden faces which can be screwed in position when they are needed, holes being provided for that purpose. This type of vice is attached to the underside of the work bench with the upper edges of the jaws flush or slightly below the
surface of the bench. It is imperative that vice with a long extension piece on the oppo the vicc should be securely fised, as by the use site side to the jaws, these being hinged of coach screws or by bolts with the heads recessed below the surface of the bench and the holes properly plugged with wood.

When circular work is to be dealt with, a pipe vice like that illustrated in Fig. 5 is the best. It consists essentially of a horizontal sole plate or base with an upright portion upon it, through which works the jaw with a $V$ shaped end. This slides in a passage way formed within the casc and closes down to a slot in the lower jaw which is similarly V . shaped. When the handle is turned, the jaws are forced together and the pipe is securely held. As such a vice is subjected to considerable twisting strains it must be bolted to a rigid bench.
In addition there are the various hand vices, ranging from that shown in Fig. 6 down to the jeweller's pin vice designed to hold fine wire while being worked. Some forms of the last named resemble a chuck in shape and action. A useful pattern for the amateur is the hand vice shown in Fig. 6. It is virtually a small

## Victorian Style in Building \& Furnishing

## Its Distinctive Features and its Good Craftsmanship

The coatribution on the Adim and Regency Styles may le referred to as immediately influencing the deve!opment of early Victorian decoration and furniture. Sec also Buhl; China: Davenpor Table; Dressing Table; , jacobean Style; Jewelry; Papier Môche; Sheraton; Tapestry Needle. work; Tudor Style; Woodworking
Much that was cumbersome, badly pro- ornament and design combined with keen portioned, crude in colour and ornament, commercialism. The rise and prosperity of the lacking in appropriate design and in meaning is associated with the decorative art and architecture of the Victorian era. It should, however, be remembered that the period was a long one, and its sixt p -four years are generally divided into Early, Mid and Late Victorian phases by certain marked features and developments.

The lirst of these phases was chicfly characterized by a continuation of the classical revival started at the end of the 18 th century and emphasized in the Adam and Regency styles. In the Mid-Victorian phase there was a great medley of the so-called artistic in
iniddle classes was accounted for by the huge output of the factorics which in turn led to the amassing of material possessions as evidence of social standing. After the Great Exhibition in 1851, china and glase ware factories and all the furnishing trades poured forth a stream of goods, and quantities were also imported, in which domestic confort and the new mechanical processes were supposed to be allied to artist ic designs. In the last Victorian phase reproductions of Tudor houses, Jacobean, Queen Anne and Sheraton furniture were in vogue. These were usually distorted with allectations of the day and stereotyped omaments.

Machine-cut decorations glued on to so-called Chippendale pieces took the place of hand carving. In the early phases colours were bright and designs were naturalistic. In the nineties curionsly conventional designs and "art" shades, lacking in purity of colour, were the fashion. The vast accumulation in most homes of unneccssaryaccessories, draperies and heavily framed pictures reached a feverish pitch. Many things of brauty, old and new, might he included in the furnishing of a room, but owing to lack of tasteful display and the jumble of other shapes and colours their decorative value was lost.
Domestic Architecture. Victorian architecture of the first two phases owes its character to two main influences. The classical style of the preceding period and the Gothic revival which was fervently advocated by Pugin, the prominent architect who designed nany churches, was connected with the planning of the new Houses of Parliament, and whose woodwork in the House of Lords is one of the really considerable artistic achievements of the early Victorian vears
Most of the public buildings and many large dwellings of the period are marred by badly proportioned pseudo classical or Gothic features, while most of the small terrace houses were very ugly in design. In the towns the dominating consideration was a so-called elegance and gentility. Typical Victorian houses are from three to five storeys in height, faced with stucco, and almost invariably adorned with a columned portico surmounted by a balcony, of which a narrower extension is carried to the boundaries. The windows are of the sash variety and the roof of slates. Balcony parapets are generally of wrought iron in a straight or curved pattern, but the square portion over the portico is often composed of stone pillars, curved or butbous, supporting a flat entablature.

To these houses there is usually attached, at the side of the entrance, an area, with stone steps descending to the basement and servants' entrance. Even in comparatively small houses of this type the pretentious portico is adhered to on a reduced scale.

Above the solid front door there is usually an ohlong fanlight. This often consists of fu!ly proportioned panes of glass, whereas the fanlights of the Georgian period were worlis of art when completed by grilles of scrolled ironwork. The hall is narrow, and, once past the foot of the main staircase, continues in a narrower passage to the top of the kitchen stairs.

Distinctively Victorian features of the dining room on the ground floor and the double
drawing room divided by doors or by a heavily curtained archway, on the first floor are the substantial marble mantelpiecca. The first flight of the stairway, up to the drawing room, is broad, with stone or wide oak steps. The flighis diminish in width with cach successive stage, culminating in the steep and narrow wooden staircase to the attics.

In the short transitional period before the Tudor revival in subur. ban and rural districts. a type of house was built in town and country that was free from the worst faults of Victorian classicism. Round arched windows are often a feature of these façades, and verandihs werc another, steps leading up to these and to the front entrances. There is cither a semi-basement or this depressing feature is absent. The portico is also absent, the front door being merely re cessed with a semicircu. lar fanlight above it. The door usually has four panels. the two upper ones being sometimes g!azed and covered with a wrought iron grille.

The ceilings of most Victorian rooms arelofty and there is a good deal of ornamental bookcases and writing tables. were the drawing moulding. Structurally, the Victorian house is room picces, chairs with gilded or ebonized often far better than its molern counterpart, frames, fine cabinets writing tables and bookthe woodwork especially being of greatly cases, walnut chiffoniers and what-nots, superior quality.

Victorian Furniture. Much of the ear!y Victorian furniture was superbly made. The more solid pieces were of mahogany and designs were gracefully curved. Cabinet making retained the excellent quality of the precerling period. Carving was little used, but moulding, were introduced and plain pancls showerl off the grain of the fine wood to advantage. In contrast to the plain mahogany pieces which included wardrobes, sideboards, large

Victorian Style. Fig. 1. The two charming examples of Victorian chairs are covered with wool tapestry needlework. The davenport writing desk was a characteristic piece of the period
interesting small tables, couches and sofas, all of which pieces continued to be made in Empire and Regency styles with brass mountings and decorated with inlay and marquetry or with buhl work Many charming small picces were made in papier mâché, japanned black, delicately painted and inlaid with mother-of-pearl
Conventions governing the choice of furniture for different rooms were much stronger than they are to day. Solidity was the keynote for the dining room in the mid and late Victorian phases, and so the dining-table had to be of large and heavy structure in keeping with the sideboard, which of ten measured 8 or 9 ft . in width, was topped by a heavily framed mirror, and had drawers and capacious cupboards below. Victorian dining-tables of the early period were often circle topped, but later they were fitted with an interleaving arrangement. Even without the extra leaf or two specimens atill in use gencrally occupy a great deal of lloor space. These are oblong in form for the most part, having solid bulbous legs attached at the four corners, the last bring rounded. Dining.room chairs are leathercovered, the backs being slightly sloped. Everything in this room was of plair and aggressively formal design, but muchpattern was introduced into the decorative scheme by the wallpaper, the curtains with festooned pelmets, draped portières, chinıney pieces also draped and crowded with ornaments and an array of Shelficld or silver plate on the sideboard, including probably a massive tea-tray and urn.

Pianos were mostly of the cottage type with pleated silk backings to tracery panels in wood. but immense grand pien ws were also seen with cases of mahogany, walnut or rose
wood. Another musical feature often to be found in the early Victorian drawing room was a handsome gilded harp. Gilding was much to the fore in the decorative scheme as the walls were sometimes literally covered with pictures in heavy gilded frames, all of one pattern irrespective of the size and style of the painting For common use chairs and sofas were upholstered in horsehair, but finer pieces were covered in damask. striped satin, brocade or tapestry needlework. Two quite charming examples of the last are seen in the chairs in Fig 1 Shown with these is a neat little davenport writing desk of the period.

In the middle of the 19th century a walnut fashion arrived and some excellent furniturc was made in the Italian and Spanish varieties of this wood. The former was particularly favoured for wardrobes and other bedroom pieces, as the grain is close and the surface takes a high polish. After this time furniture makers became obsessed with the suite, and many bideous sets of furniture for drawing room, dining room and bedroom were designed, and so well made that they still exist almost unimpaired.

Early Victorian bedrooms in well-to-do households were charmingly and suitably furnished. They were characterized by clear bright colour, crisp silks, chintzes and muslins for curtains, bed and dressing-table draperies, and usually excellent carpets with floral patterns or wreaths on dark grounds. Woodwork was painted in colours to which the polished mahogany furniture formed an agreeable contrast.

With the late sixties arrived the large and cumbrous suite, the stuffy upholstery and the heary curtains. Bedrooms as well as sittingrooms were crammed with superfluous ornaments. Fig. 2 is a good example of the bedroom chimney piece of the mid-Victorian period, and also of the chaotic effect of too many patterns so characteristic of the day. A charning little papier mâché table is doing duty as an empty grate screen, but it cannot be appreciated with the designs of the pierced fender, ugly tiles, and floral brocade drapery fighting against it, while the domes of wax flowers in turn kill the delightful pieces of Staffordshire pottery.

While many of the productions of the art crafts were as inartistic as are some of the specimens turned out to-day, and as some have been in most other periods, the Victorian output of these things was so vast that collectors are now finding much that is delightful and amusing among the treasures preserved particularly from the earlier work. Examples are also being widely copied. Apart from the undoubted beauty of the Victorian papier mâché work and exquisite coloured glass, minor crafts were admirably executed. Paper patchwork (see page 914), which was popular in the previous century, had a continued vogue as also had needlework and tapestry pictures. The Berlin woolwork of a later phase was crude in colour and design.

Beadwork in colour ${ }^{-1}$ class beads was introduced into upholstery covers and widely used for fire screens and purses. Silhouettes and tinsel work pictures of early Victorian theatrical celebrities are now eagerly sought in curio shops, as also are the pretty or quaint specimens of Victorian jewelry, the tea caddies and intricate workboxes. The gay colours and ingenious patterns appeal to modern tastes, and certain of the pieces and ornaments discreetly chosen look particularly well in the plain settings of to-day.
VICTORIA PLUM. One of the best plums in cultivation is the Victoria, which succeeds well in pyramid, standard, or bush form, and will give good crops on a west wall.

As a preserve fruit the Victoria is unrivalled; even the thinnings of green and immature
fruit make excellent tarts. Unfortunately this ingredients by degrees. When the icing is ready variety is subject to the silver leaf disease, for which there is no cure. See Plum : Pruning.

VICTORIA PUDDING. This usually makes an excellent substitute for the more expensive kinds of Christmas pudding. When intended for that purpose it is a good plan to add $\& \mathrm{lb}$. raisins and two or three apples minced.

Boil together $\frac{1}{2} \mathrm{Ib}$. potatoes and the same quantity of carrots. When they are tender chop them very finely, add to them $\frac{1}{2} \mathrm{lb}$. finely chopped beef suet, $\frac{1}{2} \mathrm{lb}$. flour, $\frac{1}{2} \mathrm{lb}$.
cleaned currants, lastly a little spice or grated nutmeg. Mix all well together and press the mixture into a well-greased mould or basin. Cover it with a cloth, put it in a pan of fast-boiling water, and boil steadily for three hours, or longer. Turn on to a hot dish and serve with any good sweet sauce. See Sugar.
VICTORIA SANDWICH. Beat ${ }^{2}$ eggs and 4 oz . castor sugar for about 10 min ., then stir in $1 \frac{1}{2}$ oz. melted butter, afterwards folding in gently $3 \frac{1}{2} \mathrm{oz}$. Glour, and I teaspoonful baking-powder. Turn the mixture into two greased shallow tins, and bake in a hot oven for 10 min . When cold, spread with jam or cream.
VICTORIA WATER LILY. Often called the royal water lily, this is the magnificent aquatic plant scientifically known as Victoria Regia. Its cultivation is quite beyond the scope of amateurs, but under suitable conditions splendid specimens have been raised from seed in Great Britain. See Lily: Water Lily.
VICUNA CLOTH. Very little of the cloth bearing its name comes from the soft, and expensive hair of the vicuna goat. It is a plain, generally dark cloth finished in a particular manner.
Vienna Bread. This term describes a light milk bread prepared with Vienna flour, and is also known as French bread. See Bread.

VIENNA CREAM. Heat $\frac{1}{2}$ pint milk and 1 tablespoonful castor sugar in a small saucepan, and bring them almost to boiling point. Then strain in $\frac{1}{4} \mathrm{oz}$. leaf gelatine previously dissolved in about 3 tablespoonfuls hot water, add vanilla or other flavouring to taste and enough cochineal to give the whole a pretty pink colour. Pour the mixture into a flat dish, allowing the jelly to measure about $\frac{1}{h} \mathrm{in}$. in depth, leave it to set, and then stamp it into neat rings with two plain cutters, one slightly larger than the other.

Have ready $\frac{1}{2}$ pint clear wine or lemon jelly, coat the inside of a mould with it, and when it is set decorate the bottom and sides with the rings of milk jelly, arranging them as tastefully as possible and setting them in place with a few drops of the clear jelly. When these, too, are firmly sct, fill the centre of the mould with a cream filling made as follows :

Dissolve $\frac{1}{2}$ oz. leaf gelatine in 3 or 4 tablespoonfuls hot water and then add 1 tablespoonful castor sugar. Whip up $\frac{1}{2}$ pint cream, and when the gelatine mixture has cooled strain it in, mixing it thoroughly. Stir in also 2 tablespoonfuls chopped glacé cherries and half that quantity of chopped glacé pineapple and then turn the mixture into the decorated mould, being careful not to disturb the rings. Leave the whole to set, and then turn it out carefully on to a glass dish.

VIENNA ICING. A good recipe for this soft icing, which can be used for decorating fancy cakes, is 4 oz . fresh butter to 10 oz . icing sugar, black coffee essence or vanilla essence to taste, and $\frac{1}{2}$ gill rum, brandy, liquetr, or sherry. The butter must be the very best and unsalted, and the sugar must be passed through a fine hair sieve. Work the butter to a cream, then add the other
a filling for a layer cake or Victoria sandwich. See Cake; Icing.
VIEW FINDER. Every camera should be fitted with an attachment by the use of which the photographer can ascertain precisely what part of the view at which he is pointivg his camera will be included on the plate or film. This attachment is known as a view finder and may take one of three forms.

The most common and least useful is that found on the great majority of small hand cameras used by amateurs, called the brilliant view finder. The amateur who wishes to produce anything more than snaps of varying success should discard it.
The image it produces is so sma! that it is impossible to see any detail in the picture, or to gain any clear idea of its composition, as it would be seen on the film or focussing screen. Again and again the amateur who relips on the brilliant riew finder with its tiny image will tind that his film is spoilt by some prominent object which he had not noticed, glaringly out of focus in the foreground.
Perhaps its most serious fault is that its use entails holding the camera about the level of the waist-line a position which is hopelessly wrong. If a scene is looked at from the knecling position, it will have a distinctly different appearance when we stand up and look at it in the normal erect position. In the first case, foreground objects posscss undue importance, and the whole perspective is partially falsified. Since things are normally looked at from eye level in the standing position, the camera should be made to look at them in that position and not as if the photographer were one of those mythical beings found on old maps with eyes in his stomach.

A much better type is the direct vision finder in one or other of its forms. An example of this is seen in Fig. 1. It consists of a double concave rectangular lens fitted to the top of the camera body in a line with the camera lens. It is of the same proportions as the plate or film used. The view at which the camera is pointed is seen in reduced size, but perfectly clearly, on the inner face of the view-finder lens, correct centring being ohtained by means

View Finder. Fig. 1. Showing a direct view finder consisting of a double concave rectangular lens ftted to the top of the camera
of a sighting pin at the proper distance away from the finder.

The camera must be held at eye level, as shown in Fig. 2. When using this type of finder the camera is almost bound to he held squarely. The complete fitting folds down on top of the camera, and can be purchased separately and added to most types of folding camera.

Another form of the direct vision tinder is the open frame (Fig. 3). Here a wire frame of the same size as the plate or film used is attached to the side of the lens mount. In some patteris it is attached to the top. At

View Finder. Fig. 2 Use of view finder as shown in Fig. 1. When this type is used the camera must
the back of the camera a aighting hole is fised, and by placing the eye to it, as clomonstrated in Fig. 3, the exact portion of the view which will be included on the tilm by the lens is seen. Moreover, the view is scen in its full natural size, so that it can be studied and the view point varied as necessary to avoid ugly foreground intrusions or other undesirable fentures. 'I'his pattern has the additional advantage that, as the frame is attached to the lens mount. its distance from the sighting hole varies with the focussing so that the finder is accurate in all positions.

## Vines and How They are Grown

## Hints on Their Cultivation in Greenhouse and Open Air

This article deals first of all with the varieties of the vine and then with the culcure of its most useful and popular forin, the grape vine. Its frult is described under the heading Grape. See also Dessert; Greenhouse; Muscat

Some of the vines are grown for their shoots being left for fruit bearing. 'l'hese ornamental leaves, which colour brilliantly in side shoots ought to be ahout 18 in apart autumn: others, valued for the sake of their on each side of the main stems it is imporfruits, are grown under glass. Although a few vurieties of grape vine may be planted on a sunny wall with fair prospect of a crop of small grapes in a favourable summer, large, well-Havoured fruits and a reliable crop are assured only by growing vines of special varieties in a glasshouse. For planting againat a sunny wall out of doors the best variety is Royal Muscadine, which bears small pale yellow grapres.

Haphazard mothods will not meet with success in the cultivation of the vine. A border must be prepared just outside the glass. house by excavating the eoil to a depth of $2 \frac{1}{2}$ feet. A laver of broken bricks is put in the bottom for drainage and the border is then filled with a compost consisting of threc parts of odd turf, chopped into pieces about the size of one's list, and one part of decayed manure, together with a sprinkling of bonemeal or special vine manure. The compost should be trodden firmly. Vines are best planted in sutunin. A hole is made low down in the greenhouse wall to allow of the stem of the vine heing passed through.

In Jannary the stem is cut back so that it reaches only to the trellis on which the vine is to bo trained. In spring two of the fresh shoots are allowed to grow, one being trained vertically up the trellis, the other horizontally along the front of the trellis. No further pruning is required until the following winter when the past summer's growth is shortened to within 2 ft . of the base. In spring the new shoots at the ends of the two branches arr. allowed to grow unchecked and a few othera are left to form side shoots or laterals, which will produce grapcs. The same routine is practised until the available space is filled, the main branches being allowed to progress at the rate of 2 ft . every year and other

VINAIGRETTE. This refers to a small box, often made of silver and occasionally of gold with an inner perfurated lid that is used for holding a sponge soaked in aromatic vinegar. It was carried in the pocket and the vinegar inhaled as a restorativo.

VINAIGRETTE SAUCE. This is made by mixing together 6 tablespoonfuls of tarragon vinegar, a teaspoonful of chilli vinegar, and 2 teaspoonfuls each of chopped tarragon and chervil. Stir these well in a basin, and season with salt and pepper. See Salad

Vinca. See Periwinkle.

Vine. 1. rrupagation oy "oyes." "Eye" suitably pottea witn its base in powdered charcoal. 3. Rooting of same. 4. Propagation in piece of turl: the eye is planted with a base of sand and charcoal dust and covered with fne rich soil. 5. Grafting a vine by approach. 8. How to top shoots : pricking out points shown by thick lines. 77 and 8. Thinning scissors and special stick for thinning. 9 Bunch suitably tifinned

| is |
| :--- |
| is | is mild.

When the grapes are the size of peass they ought to be thinned; this is done by cutting out all the smallest berries and those in the middle of the bunches with n pair of scissors having long pointed blades. A further thinning will be necessary to give the berries room for lull development. When the grapes begin to change colour a dry airy atmosphere is again necessary

If the rinc is grown in an unheated greenhouse it will start into growth later than if the glasshouse is heated and the grapes will ripen later in the summer During dull wet weather great care must be taken to ventilate correctly and to keep the air of the greenhouse as dry as possible to prevent an attack of mildew : it is most important also to attend to summer pruning in the way advised to prevent overcrowding.
The best grape to grow in an unhcated glass house is the varietv known as Black Ham hulgh: this variety is also well suited to a heated glasshouse where, however, others Thay be planted. Those most easily managed are Alicanté, Gros Colmar, Madres tield Court and Fos ter's Seedling (a pa!e yellow grape). Oi her lirst rate grapes which need soinew hat skilled attention are Lady Downe's. Muscat Hamburgh. Mrs. Pince and Muscat of Alex. andria: the last na med is a pale yellow grape: s,enerally regardeld as the most delifions of all which requires rather a higher tem perature than most others to bring it to 50 degrees in February and cluring the spring months. As the temperature rises out of doors the ventilators must be opened to prevent the glasshouse becoming excessively as the day advances if necessary. In the afternoon, an hour or so before the sun has ceased to shine on the roof, the ventilators ought to be closed, at the same time the Hoor and walls should be syringed. The vine Hourishes in a warm moist air excepl when the bunches are in flower: then the glasshouse bunches are in flower: then the glasshouse mild perfertion.
Propagation. Vines are propagated by eyes or buds. In Junuary a piece of shoot of
further risk that mildew will set in and the grapes will not ripen properly.
In winter, all side shoots, whether they have borne fruits or not, nust be pruned to within two buds of the base of the past summer's growth. If in spring both buds sturt into growth one of the shoots, the weaker of the two, must be rubbed off. Summer and winter pruning in the way described is an important detail in the cultivation of the vine, and success depends chietly on its being carried out. As the years pass this hard annual pruning will result in the formation of woody swelling, called spurs, at the base of the side shoots.

## Ventilation and Thinning

Other details which need attention are ventilation, the regulation of the temperature and thinning the bunches. If the glasshouse is heated, a night temperature of 45 degrecs should be maintained in January and one of
the previous year's growth is cut off : it should be about. $1 \frac{1}{2}$ in long and contain a bud. If set singly in small pots of light soil, placed in a propagating case in a heated g!asshonse and kept moist, these eyes will form roots: they are subsequently potted in smal! pots and repotted as becomes necessary until they are in 8 in . or 9 in . pots. In late sum. mer when growth is complete they should be placed out of doors so that the wood may become well ripened. autumn the young vines may be planted in a border or repotted in 12 in . pots in which they will bear fruits: the stem; or branches are trained on thick bamboo canes inserted tound the edges of the pots. They need similar treatment to that already described. In December all loose bark should be peeled off the vine stems, which must then be treated with a biush dipped in the Gishurst compound preparation : this will help to keep them free from the attacks of pests.

Pests of the Plant. Red spider is a pest which attacks the lower surface of the leaves and disfigures and weakens them ; it is most likely to be troublesome in a dry, warm atmosphere Syringing the lower side of the leaves with salt water, 1 oz . in one gallon of water, is recommended. Mealy bug is the most serious pest ; it can be killed by using a brush dipped in methylated spirit, but great care must be taken not to touch leaves or huds or they will be ruined.

Mildew is a troublesome plant disease to which vines in an unheated glasshouse are particularly liable. It spreads most quickly in a damp atmosphere, therefore if mildew appears the greenhouse must be kept dry and airy. Affected leaves should be "dusted" with sulphur. Great care must be taken not to let the trellis become overcrowded with shoots and leaves. Summer pruning should be practised in the way already advised.

Ornamental vines are handsome leafy climbing plants for covering trellises, arbours and pergolas, and the self clinging Vitis (ampelopsis) Veitchii is invaluable as a wall covering: its small leaves turn crimson in autumn. The best of the large leaved ornamental vines which become beautifully autumn-tinted are Coignetiae, quinquefolia (Virginian creeper), Thompsoni, Thunbergii, Engelmanni and Vinifera purpurea (the purple leaved vine). Vitis Henryana. which has small green and white leaves, is suitable for planting on a wall in mild districts. All these vigorous plants thrive in ordinary well tilled soil.

VINEGAR : Its Uses. Vinegar is a solution of acetic acid in water usually darkened by adding colouring matter. It may be prepared from malt, wine, cider, sugar, wood, and other substances. The ordinary brown vinegar is made from malt. Most French vinegar is colourless, being obtained from the fermentation of light wines.

Besides its use as a ta'ile condiment, vinegar is employed in coskery for giving a piquant flavour to savourics and sauces, for dressing

beautitu border plant
salads and for pickling. Various dishes are prepared with it, as, for example, herrings cooked and soused in vinegar. Tough meat is made tender by stecping in vinegar and water before cooking
It is not difficult to make herbHavoured vinegars at home, and it is useful to have various flavours in the store cupboard. Tarragon vinegar is made thus: To $\frac{1}{4}$ peck tarragon leaves add $\frac{1}{2}$ gallon white vinegar. Leave it in a covered jug for two weeks, then strain it through flannel ; return it to the jug. Dissolve in it a good pinch of isinglass in order to fine it. Afterwards bottle and cork it down.
For chilli vinegar add 1 oz . ground chillies to 1 quart white wine vinegar, put it in a covered jar, and leave it for two wecks, shaking it each day, then strain and bottle for use. To make horse-radish vinegar scrape 3 oz . horse-radish, add 1 oz.ghredded shallot and 1 dram cayenne pepper. Put al! into a jar and pour over it 1 quart white wine vinegar. Cover it closely and let it stand for two weeks, shaking it occasionally, then strain and bottle it.

Cayenne vinegar is useful when a hot scasoning is required. Put $\frac{1}{2}$ oz. cayenne pepper into a jar and pour on it l pint white wine vinegar. Cover it closely and leave it for three weeks, shaking it cvery two or three days. When ready, the liquid must be poured off gently into a bottle or strained through a piece of fine muslin.

Orleans vinegar, prepared in considerable quantities in the Orleans district, is a variety of white wine vinegar suitable for table use and for toilet preparations.

Vinegar is considered to help in the digestion of oily or fatty foods. It should, however, be

Viola Culture. 1. Cutting: $a$ how to prepare: $b$, depth to plant. 2. Natura plantlet : $a$, root growth; $b$, depth to plant. 3. Type of cutting to avoid. 4. Violas from seed : $a$, glass ; $b$, cross sticks ; $c$, sandy soil; $d$, compost; $e$, leaves f. crocks. 5. Seedlings transferred to ahaded cold frame: $a$, ventilating block ; $b$, ahading material. 6. Old plant trimmed to provide cuttings. 7. Soil preparation for cuttings: $a$, sand; $b$, ine losm; $c$, ashes; ${ }^{a}$, gub-soil. 8. Dibbed hole with sand at base. 8. Cutting suitably planted
used in strict moderation, as it interferes with digestion, and may set up irritation of the stomach if taken too constantly or too freely Vinegar is often taken by the ignorant as a remedy for reducing the weight. It should be clearly understood that its use for this purpose is utterly unjustifiable, as the only way in which vinegar can make one thin is by seriously harming the digestion. See Acetic Acid; Pickle: Salad; Sauce.

VINEGAR CAKE. Take 1 lb . self-raising flour, 4 oz. each margarine, sugar, raisins, and sultanas, 1 teaspoonful bicarbonate of soda 1 breakfastcupful milk, and 2 tablespoonfuls vinegar. Rub the margarine into the flour add the sugar and the dried fruit, and then the bicarbonate of soda dissolved in the milk. To these add the vinegar, mix all together, and then bake in a moderate oven for an hour

VIOLA: The Flower. This is the botanical name of the group that includes the viola or tufted pansy, the ordinary pansy and the violet. Some of the violas are charming rock garden flowers, while the larger-flowered sorts are invaluable for filling spring and summer flower beds. The modern race of large-flowered violas originated by cross-

Viola. Tiny gellow nowers of the low growing rockery plant
breeding between Viola cornuta, a Pyrenean plant, and the pansy.
They flourish in ordinary well-tilled soil, and are propagated by cuttings inserted in sandy soil in a cold frame in September; during the winter in mild weather the frame must be ventilated freely. The plants are set out of doors in April, and will bloom throughout many summer weeks if the dead blooms are picked off and the soil is moist. They are also easily raised from seeds sown under glass in spring,. Some of the best varieties are: Primrose Dame, pale yellow; Maggie Mott, lavender; The Swan, white; Moseley Perfection, yellow; W.H.Woodgate, pale blue ; Archie Grant, purple blue; Mrs. Chichester, white and purple ; and Redbraes, yellow.

Viola cornuta is a plant of tufted growth which bears small flowers in profusion; there are varieties with blooms of purple, rose, and other colours which are most useful for planting in rose beds and flower borders.

Of the species or wild types suitable for the rock garden the following are very charming flowers: calcarata, lavenderblue; gracilis,
purple, and its fine variety Purple Robe : and lutea yellow. These ahould be planted in gritty, loamy soil in slight shade.
VIOLET. This favourite garden flower pays for good cultivation If the plants areleftun. disturbed for vears the blooms be. come small. It must be planted in decply dug soil enriched with manure in a slightly shaded position; a border facing west is ideal. In May the old plants should be lifted and separated into
 picces, the best of thesc being replanted. Single varieties are set at 15 in. apart, double varieties at 12 in . apart. During the summer months the soil between the plants should be hoed frequently to keep down weeds, and all runners must be cut off.
To ensure fine flowers the violet bed ought to be replanted annually, or, at all events, every two years. Some of the best varicties aro Princess of Wales, Czar, California, and La France, violet blue; and White Czar, white. These are single flowered. Good double violets are Comte de Brazza, white ; de Parme, lavender; Marie Louise, mauve purple; Mrs. Astor, rosy heliotrope: and Neapolitan,
lavender. Admiral Avellan, red lavender. Admiral Avellan, reddish mauve, and Coeur d'Alsace, pink, are two pretty single violets of unusual colouring.

To obtain violets in winter some of the plants should be lifted and planted in a bed of soil in a cold frame in September; the frame inust be in a sunny position; it should be ventilated frecly in mild weather in winter.

Violet Culture. 1. Plant with rooted runner (a). 2. Runner planted : u, fine soil with sand around roots. 3. How to lift clumps. 4. Trimming same for

It is an advantage to make up a hed of fresh, dry leaves in the frame beneath the soil in which the violets are. See Dog's Tooth Violet.

VIOLET CRESS. The hardy annual that is called violet cress or Ionopsidiun is of miniature growth, and produces tiny flowers of white tinged with purple. It should be sown in spring where the plants are to bloom in summer, in light soil in partial shade in the rock garden.

VIOLET GROUND BEETLE. This creature is a little friend to the gardener, and therefore should not be destroyed. It is one of a large family of beetles, the parents and larvac of which run about the surface of the soil devouring grubs and other pests. This beetle is about 1 in . long; and may be recognized by its colouring of violet-black.

VIOLETTA. This is a small-flowered viola, of which there are many varieties suitable for the rock garden or the front of the Hower border. See Viola.

VIOLIN. To the eye the violin presents three principal parts : the body, which is the resonating chamber; the neck, upon which the finger-board is fixed; and the strings, which extend from one end of the instrument to the other. From a constructional point of view it comprises no fewer than 57 distinct pieces of wood, fitted and glued together, in addition to which there are 13 movable fittings, such as strings, pegs, the bridgn, etc.
The violin is an instrument which demands not only absolute perfection of workmanship, but also most careful adherence to those principles of measurement and proportion exemplified in the extant sjecimens of Stradivari, Amati, Guarnieri, and the other masters. It is possible for good workmen to turn out excellent modern violins, but the merit of these is always according to the personal care bestowed upon each instrument, a care which is necessarily lacking in the case of the cheap fiddle produced by the thousand
Details of the Body. An examination of the hody will show that the wood employed is not the same throughout. There is a reason for this. The back and the belly exert a mutual influence, and therefore if the former gives a . hard, metallic sound when trasted by rapping it with the knuckles it is necessary to counteract this by choosing for the belly a somewhat softer wood.

Besides the density of the wood, there are other factors which enter into calculation. The harder the wood, the thinner it can be worked to promote frecdom of vibration, and this thinning of the plates is an iniportant detail of the workinanship. Though other woorls, such as sycamore, can be used, maple is preferably chosen for the back, as also sometimes for the neck and ribs. The belly and the inside fittings, such as the hass bar, the blotks, the sound-
post, ete., are of pine. The age, density, and grain are all-important considerations in sclecting the wood. The finger-board, the tailpiece, and the pegs are of ebony.
The body of the violin consists of the back and the belly, which are united by the ribs, but it would be too frail to withstand the strain of the strings without some internal adjuncts. These are first of all the blocks, four of which are glued in the corners next to the waist of the violin, with two more at the top and bottom respectively; but the most important fitting is the sound-post, which is placed about $\frac{1}{4} \mathrm{in}$. or less behind the right foot of the bridge. This resists the thrust of the bridge upon the belly, and plays an indispensable part in transmitting the vibrations of the strings to the body. Its thickness, density, and exact position are factors which vitally affect the tone.
The linings are narrow strips of pine, which run all round the inside edges of both back and belly. affording a wider surface for glueing to the ribs, and thus strengthening the structure. The last inside fitting is the bass bar, which is tixed longitudinally to the belly close to the left sound-hole. Mention must also be made of the purfling, the thin black lines of stained plane wood which follow the outlines and obvinte any possible danger of the edges splitting. Lastly come the $f$ or sound holes, which are cut in the belly

Neck and Varnish. The neck is fixed to the upper end of the body, and terminates in the head or scroll. Immediatcly below the scroll is the peg-box, the sides of which are picreed with holes to receive the four pegs. The slight projection at the back is called the nut. Upon the upper surface of the neck is fixed the fingerboard, which is slightly convex, and projects over the belly to within an irch or so of the top of the $f$ holes. The strings extend from pegs, round which their one end is coiled, and pass over the bridge to the tailpiece, in which the other end is fixed. The bottom of the tailpiece has a loop of stout gut, which passes round the tailpin on bottom rib.

This description of the parts of the instrument may be completed by mentioning the varnish, which is put on after the desired yellow, red, or brown has been applied to the wood in the form of a wash. Spipit varnish is often used for cheap violins. Oil varnish, though slower in drying, is more lasting.

The bridge transmits the vibrations of the strings to the belly, and, speaking generally, a heavily built instrument will take a finer bridge than a lighter one. Its position is of extreme importance. The correct place for its two feet is exactly between the nicks on the inner edges of the $f$ holes. The feet must also be adjusted exactly to the curve of the belly. When properly placed, the right foot will be in line with the sound-post, and the left foot immediately over the centre of the bass bar

Tuning the Strings. The four strings are tuned in fifths as follows:

The second string $A$ is the standard by which the others are regulated As they are a!l of the same length, the differences in pitch have to be secured by differences in thickness and density, while the fourth string $G$ is wound round with silver wire. The requisite tension is obtained by turning the pegs so as
to stretch the strings With experienced performers this is done by the left hand, while the right band is free to test the pitch with the bow, but in the case of beginners the instru ment is held by the neck resting it against the kneo, while the pegs are manipulated, the atring heing twanged from time to time until the pitch is correct The final test. however. is alwaye made by the bow

To fix a new string, knot one end, slip it through the proper hole in the tailpiece, and draw it through the slit, where it will be held by the knot Thread the other end through the small hole in the peg, pass it under itsell and turn the peg, which should be pressed inward as it is turned The rest of the coil may then be cut off The $G$ string is sold of the proper length only The pitch of the $A$ string having been adjusted to the pitch required by circumstances, the $D$ string is tuned with it, and then the $G$ string below that. Finally the first string is tuned with the sccond string In cach instance make sure that the fifth is absolutely perfect before proceeding
Holding the Instrument. The violin is held with the left hand encircling its neck, but so that the palm does not touch it The end of the instrument rests on the left collarbone, where it is kept in place by a sufficient pressure from the performer's chin In order to induce greater security of tenure, some players either use n chin-rest fixed to the violin or place a pad upon the collarbone: but this laiter, at any rate, would seem to militate against resonance
The neck of the instrument resting in the hollow of the thumb. the fingers are beld over the finger board, so that the first finger if pressed down will produce $F$ on the first string, the second finger $C$ on the second, the third finger $G$ on the third, and the fourth finger D on the fourth string

The bow is held in the right hand The thumb must touch the raised part of the nut, and the lingers must be rounded slightly over the stick Possibly, with some hands, the little finger will experience difficulty in doing this, but if it can be managed it will be of great advantage in forte playing. The bow crosses the strings at right angles between the bridge and the end of the fingerboard, and in order to secure an even, steady tone it should preserve that position in every respect. The action of the right arm should be without stiffess, and special attention must be given to the freedom and independence of the wrist, the forearm. and the upper arm.
The Music. Music for the violin is always written on the treble stave with the G clef. Bowing is always indicated exactly, otherwise each note receives a separate bow. The combinations of slur and dot, etc., are too numerous to be treated in detail here, and full information must be sought in violin schools; but the chicf thing to he remembered is that all the notes under one slur are to be performed by the same stroke of the bow. A down bow is indicated by and an up bow by $\Lambda$.
The only other notation that need be mentioned here is that for harmonics. A smallo placed above a note means that it is to be played as a natural harmonic. If artificial harmonics are desired, there is a double notation; the notes which have to be pressed down are given in the usual notation, while for the barmonic there is a diamond-shaped note joined to it by the same stem. thus:

VIRGINIAN COWSLIP. This is the popular name of a hardy herbaceous perennial named Mertensia pulmonarioides. It grows

18 in high and bears blue flowers in May It flourishes in ordinary well-drained soil and is incrasaed by division in Feliruary.

VIRGINIAN CREEPER. The botanica name of this favourite hardy climbing plant so often planted on house walls, is Vitis (ampelopsia) quinquefolia; its large lobed leaves eolour brilliantly in autumn. The amall-leaved Vitis inconstans (Ampelopsis Veitchii) is a greater favourite because it is self-clinging, and even more brilliantly tinted. These climhers thrive hest on sunny or only

Virginian creeper. small eaves of the seli-clinging variety known as
slightly shady walls. It is necessary to support the sclf-clinging kind with a few pea sticks until it has started to cling to the wall. The large-lcaved Virginian creeper should be trained to a trellis of wood fixed against the wall. Planting may he done in autumn or spring Propagation is by cuttings placed in a frame in autumn or by small pieces of growth, each containing a bud, set in a heated greenhouse in early spring.

VIRGINIAN POKEWEED. This vigorous hardy herbaceous perennial is suitable for the wild garden or large border. The stem reaches a height of 6 ft . or more and the small white flowers are followed by deep purplish berries ; it is most ornamental in early autumn. Propagation is by seeds sown out of doors in epring. The roots are poisonous.

VIRGINIAN STOCK. This low growing hardy annual blooms in about 6 weeks after the seeds are sown out of doors in March or April. It is a pretty little plant for an edging to a llower border, the blooms being crimson, rose or white according to the variety chosen. Its beauty is rather short. lived, but another sowing may be made to provide blooms in late sumimer. Its lotanical name is Malcolmia maritima.

VIRGIN'S BOWER. This is the popular name of a rampant climbing plant named Clematis flammula. It beara a profusion of small white fragrant flowers in late summer and is useful for covering an arhour or trellis. It flourishes in ordinary soil.

Ampelopsis Veitchii, valued by the gardener for its decorative effect and beautiful autumnal colouring

VISCARIA. This is a very showy hardy annual with rose, crimson, white, or purple flowers. It reaches a height of about 12 in ., thrives in ordinary soil in a sunny position, and blooms in summer from seeds sown out of doors in March and April. As with all annuals it is most neccssary to thin out the seedlings to give them room for development.
VISITING: The Etiquette. The usual method of kceping up with friends who live at a distance is to stay with them or one's own home. Few visits cxceed a fortnight in length and a week-end is the most usual. The invitation naturally depends upon the circumstances both of host and guest, and must be adapted to suit them. l'eople who possess cars often enjoy weekends, which might prove too expensive for a guest to whom the railway fare is a consideration only to he justified by a longer visit.

The hostess will naturally invite people at the time when it is most convenient for her to have them, and if wise will also nake the invitation a definite one. She will ask the gucst for a week, a week-end, a fortnight, or whatever period may he suitable. The guest should seldom stay on after that periorl, even if pressed to do so, unless something has intervened since the arrival to make an extra day or two advisable.
If asked for a week-end the guest should assume that be is not expected before lunch time on Saturday, He will also assuine that his departure early on the Monday is expected. If asked vaguely for a few days the visit should always stop short of the week.
The time of departure is necessarily varied by circumstances. If the guest is lcaving by
 suitable for garden borders
car, as a rule an hour after breakfast is con- portion, either in the form of thick sheet or venient, but if returning to business after a week-end there may be a specially early train to catch which should be understood before, or soon after, arrival. Other departures may be regulated by convenient trains for cross country journeys, but in any case it is best to have the matter clearly settled in advance wherever this is possible.

At the conclusion of a visit of some days a tip of 5 s . is usual to the parlourmaid and also to the housemaid attending on the rooms. The chauffeur would have the same when leaving the guest at the station. Where there is a butler or single-handed manservant instead of a parlourmaid, the same tip would be usual. In the case of a young unmarricd gucst the tips to women servants are often reduced to 2 s .6 d. , and tips to manservants may not be expected.

In larger houses the question of tips becomes rather more expensive for a man. He may be expected to give 5 s . to 10 s . to a footman who acts as valet as well as tipping the housemaid, etc.
VITAMIN. Certain complex substances which exercise a profound influence on the metabolism of the body are known as vitamins. Six are definitely known to exist, and are described as vitamin A, B1, B2, C, D and E respectively. Vitamin A and vitamin D, which appears to occur in close association with it, are not soluble in water but dissolve in fats. They are not easily destroyed by heat. The former promotes growth and the latter prevents rickets, and to a lesser extent promotes growth. Vitamins B1, B2 and C are soluble in water and are more easily destroyed by heat, espccially vitamin C. The absence of vitamin Bl from a diet leads to the development of beri-bcri, the absence of B2 to the development of pellagra, while the absence of vitamin C results in scurvy.
The vitamins originate in plant life and are present in the fresh tissues of animals that live on plants, so that they occur in varying proportions in both animal and vege table foods. Under the heading Diet (q.v.) there appears a list of foods with the vitamins they contain, and the amounts. It will be understood that vitamin D is included with fat-soluble vitamin A.

VITEX. The only kind of vitex in general cultivation is Vitex agnus-castus, a shrub suitable for planting against a sunny wall in mild districts. It bears bunches of white flowers in September, but is not likely to bloom freely in a sunless season. It can be propagated by cuttings in summer and should be hard pruned in February

VIVARIUM. This is the name given to a receptacle for housing small semiaquatic animals and insects, or butterflies. It is generally supplied with a small pond, rockery, ferns and other plants. The construction is on similar lines to that of an aquarium, but it need not be all watertight, the usual form being illustrated in Fig. 1. It is hardly worth while making a vivarium of less than 30 in . by 15 in . with a height of 30 in ., as it would be difficult to arrange for a small pond as well as a selection of ferns and other plants. Teak can be used for the upper portion, which forms a frame for the glass, and zinc for the lower
a lining to a shallow wooden box.
The casc should be madc in thrce parts, as indicated in the section at Fig. 2. The base is a trough measuring 32 in . by 15 in . by 6 in ., as at A. This supports a rectangular framing (B), open top and bottom, filled on the four sides with glass and made to a height of 18 in . The framing is covered with a top (C), with sloping sides, 6 in. high, framed up to match the lower framing and filled in with glass in the same way, but it has an opening at the top 18 in . by 6 in . covered with perforated zinc sheeting.

Several ways of making the framework are illustrated in Figs. 3, 4, and 5. The trough is made of cither deal or hardwood from $\frac{3}{4} \mathrm{in}$. to 1 in . thick, with the corners butted and nailed, or dovetailed. The lining should be of thin sheet zinc, with the corners soldered
The upper portion should fit on top of the trough with an overlapping half-round bead around the bottom edge if the framing is of wood, or a flange if of metal. The latter material can be used, as at Fig. 3, by folding it over to enclose the glass. The top portion of the frame should be in two strips so that the glass can be slipped between them. The corners of the framework should be soldered together. Another method is to use anglepieces, as in Fig. 4, the same method of inserting the glass being used. Fig. 5 illus trates how the frame can be made up of wood. A frame is formed of 1 in . square material, a groove being cut for the glass, and the corners joined with mortise and tenon joints. The top portion is made to mat the lower portion, the 18 in . by 6 in . ventilating opening being allowed for, the sides filled with glass, and a piece of perforated zinc attached to cover the top. For hints on setting out the angles for the mitre joints of top framcwork, see Mitre.

The pond can be formed with a shallow earthenware dish, the rocks made with coke dipped in cement, and the trough filled with soil. See Aquarium.

Vivarium. Fig. 1, Case in teak, zinc and glass for small semiga a 5 Difer mals.

VOICE : Its Care. The voice is the sound that is produced by the vibration of the vocal cords of the larynx. These are set in motion by waves of air breathed out from the lungs. The pitch of the vocal sounds depends on the rate of vibration. Sounds produced in the larynx are modified by the movements of the lips, tongue, ctc. The quality or timbre of the voice depends upon secondary vibrations, overtones or harmonics, superimposed on the primary vibrations. The loudness of the voice depends chiefly on the quantity of air which is employed in order to set the vocal cords vibrating.
Men have deeper or lower pitched voices than women because, as a rule, they have longer vocal cords. The breaking of the voice, which occurs at the change from childhood to adult life in the male, is due to the rapid growth of the larynx at this time, and the temporary lessening of control over the muscles which govern the tension and rigidity of the larynx.
Loss of voice and gruffuess of the voice or hoarseness may be brought about by anything which interferes with normal movements of the vocal cords. Paralysis of the nerves supplying the cords, growths on the cords, ulceration, catarrhal inflammation, etc., all may interfere to a greater or less extent with the production or with the quality of the voice. See Laryngitis; Larynx ; Throat; Tonsillitis.
VOILE. There are both silk and wool voiles, but thesc arc unimportant in comparison with the cotton voiles. All are light in weight and open in texture.

Crispness is a virtue in cotton voiles, plain or fancy; double voiles, as they are sometimes called, crease less easily than the soft, clinging kinds, last longer, and require washing less frequently. Especially when buying self-coloured voile, care should be taken to choose the harder-fceling variety. Patterned or plain coloured cotton voiles makc excellent glass curtains for bedroom windows.

VOL-AU-VENT. This refers to a round or oval case of puff pastry which, after baking, is filled with some delicate ragout of chicken, sweetbread, lobster, or other fish. Sometimes quenclles of chicken are mixed with the sweetbricad. The sauce used is always rich and usually flavoured with mushrooms and truffles. When served as a sweet the pastry case is filled with fruit.
To make a good vol-au-vent 1 lb . puff pasto will be required. After giving the paste six turns, roll it out $\frac{8}{4}$ in. thick and cut it to an oval shape. Place the case on a baking-sheet rinserl with hot water and brush the top of it with egg, then mark it with a cutter or sharp knife within about $\frac{3}{4} \mathrm{in}$. of the cdge all round to form the lid. Put a hoop of white paper 2-3 in. high and a little larger than the case around it. Bake it in a hot oven from $\frac{3}{4}$ to 1 hour.
When baked, remove the lid, scoop out any soft pieces of pastry, brush the inside of the case with egg, take away the paper and return the pastry to the oven for a few minutes. Have the filling ready and well heated, then fill the casc and cover with the lid. It is better to dish the vol-au-vent before filling it.
Turbot Vol-au-vent. A vol-au-vent case filled with cold boiled turbot reheated in some white sauce makes a good luncheon dish. Prepare the pastry case as directed, break the fish into Hakes, rid it of skin and bone, and then moisten it with the sauce, made from fish stock. Add n few shelled shrimps and seasoning to taste, heat the mixture thoroughly over the fire, and then turn it into prepared case. Serve very hot.

Turkey Vol-au-vent. Small vol-au-vent cases may be filled with a savoury mixture of turkey and ham. While the cascs are baking, mince the remains of some cold cooked turkey, add to it about a quarter of its weight of grated ham, a little white sauce and a spoonful of thick cream. Heat these together in a small
pan, season them to taste with salt. pepper, and mace, and then turn them into the hot cases. Serve them at once.
Fruit Vol-au-vent. A good sweet is made by putting 3 desscrtspoonfuls Demerara sugar into a saucepan containing $\frac{3}{4}$ gill water and allowing the two to boil for 5 min . or until a thick syrup is formed. Add 1 lb . damsons, cherries, plums or other suitable fruit, cook them very gently until they are tender, and then leave them to get cold.

Make the vol-au-vent case, as previously directed, take out the inner circle of pastry.

Frait Vol-au-Vent. an attractive sweet
and when the case is cold fill it up with the fruit, kceping back some of the juice if too moist.
Mix a few drops of vanilla and a sprinkling of castor sugar with 1 gill of cream, whisk the whole until it thickens, and then shake it on to the fruit, decorating the top with one or two damsons, cherries, or neat picces of fruit if a larger kind is used. If liked, a teaspoonful of lemon-juice can be added to the flour when it is mixed with water; this counteracts the richnces of the pastry. See Pastry : Sauce.
VOLT. In electricity the unit of elcctromotive force or electrical pressure is termed a rolt. It is that pressure which will drive a current of one ampere through a resistance of one ohm. See Electric Light.

## Voltage. See Electricity.

VOLTMETER : Its Uses. The instrument known as a voltmeter is used for recording the voltage or pressure of an elcctric current flowing in a circuit. The watch pattern voltmeter is convenient for testing the voltages of accumulators or other sources of small voltage supply. It consists of a metallic casing enclosing the coils, etc., and fitted at its bottom end with a pointed lug which forms onc of the connexions. The other connexion is a short length of flexible wire which passes through a hole in the knob to which the ring is fitted. The outside end of the wire is finished off in a sharp-pointed metal end.
To use the instrument it should be inspected to see if it requires connecting to a circuit a definite way round. If this is the case, a plus sign is usually to be found near its appropriate terminal. This terminal should be placed on the positive side of the battery or circuit under test, while the negative side of the battery is joined to the negative side of the instrument. To obtain an accurate reading the voltmeter should be held vertically. Good connexion is made by scraping and pressing the pointed ends of the voltmeter connexions whiile a reading is being made.
As the voltmeter is required to read the difference of potential between two points in a circuit, it is placed in parallel to the circuit containing the resistance causing the potential drop. In this respect it differs from an ammeter, which is a low-resistance instrument, and, as it measures the total current flow it is wired in serics to the circuit.
Testing H.T. Batteries. Only high resistance instruments should be used for testing the voltages of high-tension batteries, otherwise an unfair load is placed upon the small cells.

In order to obtain an accurate indication of the state of a battery used for a wirelees set all voltage readings should be taken with the battery delivering its normal current to the valves. "Open circuit" readings are misleading, because the cells tend to recover after a period of rest, but when current is consumed the voltage gradually falls to a steady value, depending upon the condition of the battery.

## The ordinary high-resistance volimeter is

 not suitable for measuring the output vollages of mains H.T. unils.
## See Accumulator: Battery.

VOLUME CONTROL: In Wireless. This is a device for adjusting the power applied to the loud speaker. A popular method of controlling the volume is to connect a highresistance potentiometer across the secondary terminals of a low-frequency transformer. The resistance of the potentiomcter should be not less than 500,000 ohms, and the connexions are as follows: Join the two potentiometer terminals (which are connected internally to the ends of the resistance element) respectively to "G." and "G.B." on the transformer. Connect the moving arm or slider (usually the centre terminal) to the grid terminal of the valve-holder. If the grid terminal is already joined direct to " G." on the transformer, this lead must first be removed.
The potentiometer method is also applicable to sets employing resistance-capacity coupling. In this case the usual grid-leak resistance betwoen the grid of the valve and grid bias negative is replaced by the potentiometer. the slider of which is joined to the grid of the valve, and the two ends of the resistance element to the coupling condenser and grid bias negative respectively. See Potential Divider.

VOLUNTEER SNOOKER. This billiard game is a variant of snooker. It can be played by two or more persons either as sides or independently. It is called voluntecr snooker because a player is said to volunteer if, when striking, the cue ball hits a pool ball which he is not on, after the first score.

In general the game proceeds in almost the same way as snooker pool. The samc 22 balls are necessary and there are no cannons. The balls are the white one, known as the cue ball. with which each striker plays, 15 red balls, and one each of the following colours: yellow, green, brown, blue, pink, and black; these six are the pool balls. See Billiards ; Snooker Pool, etc

VOMITING. The forcible expulsion of the contents of the stomach through the mouth, vomiting is generally preceded by nausea and with this a free flow of saliva. The first thought on the occurrence of vomiting will generally be that it is due to some disturbance of the stomach itself causcd by the ingestion of unsuitable food or of some irritant poison, but there is a very large list of possible causes, many of which have no connexion whatever with the digestive apparatus. Those that have such a connexion, apart from gastric affections themselves, include irritation in the pharynx, irritation or obstruction of the intestine, appendicitis, gall-stone, and other affections of the liver and gall-bladder.

On the other hand, vomiting may occur in the eye disorder known as glaucoma, and in some car disorders in which there is disturbance of the apparatus concerned with preserving balance; it is a common incident in pregnancy; it usually occurs when there is renal colic ; it may be an early symptom of meningitis, and is caused by tumours in the brain.
Information regarding the cause of vomiting may often be derived from an examination of the vomitus, or vomited matter. Frequently this will consist of undigested food simply, but when vomiting is caused by corrosive poisons, the vomitus may contain shreds of stomach-lining and blood. In gastric ulcer and
cancer there is also blood, but there are other causes for blood vomiting. Bile is often found in the vomit, and sometimes wrongly supposed to be the cause of the vomiting, when what has happened is that bile has been forced into the stomach by the muscular contractions that caube vomiting.

The treatment of vomiting depends on the cause, and in many of the conditions above mentioned treatment will have to be directed to other things than the vomiting, which is mercly incidental and relatively unimportant. When the cause is irritating food or something of the kind, it is desirable to give large draughts of tepid water. This washes the stomach out, and makes the act of vomiting less distressing. Sips of hot water may check vomiting, though sometimes sips of iced soda water are more successful. In persistent vomiting during fevers, sips of iced champagnc often prove beneficial when other remedies have failed. Counter-irritation over the pit of the stomach by applying a mustard plaster is another useful measure in some instances.

Many drags, including bismuth, morphine, dilute hydrocyanic acid, and others are used in treatment. A convenient remedy may be found in a single drop of tincture of iodine in a tablespoonful of water, the dose to be repeated every 15 minutes for tive or six doses. See Biliousness ; Emetic ; Gastritis; Indigestion; Morning Sickness; Nausea; Poisoning : Sea .Sickness.

VOTE : How to Secure. The qualifications for the parliamentary vote were altered by the Act of 1923. At the present clay a vote of this kind can be exercised practically by all men and women over 21 years of age, provided they are British subjects. Such persons must have resided for six months at the house in the constituency in which they vote, or must have occupied business premises for that period. This is the qualifying period which ends on Jan. 15 or July 15 each year.

A person can vote in two constituencies but no more. For instance, a man or woman can vote as resident and also as occupier of business premises, provided the two are in different constituencies. He or she can also vote for one of these, and, if qualified, for a university In the case of universities the vote can be. exercised by those who have taken their degrecs. Women can rote for a university that does not admit them to its degrees, provided they have passed the necessary examinations. Special arrangements are made regarding the rights of soldiers and sailors to vote. They are registered in the constituencies for which they would be qualified if they were not away on service. This condition applies not only to soldiers and sailors on full pay, but to merchant seamen, pilots and fishermen, and to those engaged on Red Cross and other work of national importance abroad. These persons are allowed to vote by proxy. The Act of 1918 allowed persons in receipt of poor relief to vote; previously they had been disqualified.

The Register of Voters. To exercise the right to vote, the person's name must appear on the register of electors. This is made up twice a year, once in the spring and once in the autumn. The former comes in force on April 15 and the latter on Oct. 15. The town clerk or clerk of the county council is responsible, under the council, for making up the register for his town or county. He decides whether or not a person is qualified to have his or her name placed on the register. Anyone dissatisfied with his decision can take the case to a county court and from there to a court of appeal. A person desirous of obtaining a vote should therefore first find out whether the name is on the register.

Voting for Local Authorities. As regards local authorities, persons, both men and women, are qualified to vote at clections for these bodies if they are 21 years of age and over,
and occupy, either as owner or as tenant, any land or premises in a local government electoral area. He or she must have occupicd the prenises for the qualifying period of six months, and the name must appear on the roll of electors. In this sense a tenant includes a lodger, provided he or she is in the occupation of unfurnished rooms.
VULCANITE. The real difference between vulcanitc and ebonite consists in the quantity of sulphur used in the manufacture. Vulcanite is made by incorporating india-rubber or gutta-percha with ordinary sulphur and lampblack in a masticating machine. It is pressed into moulds and heated in a steum oven at a temperature of $315^{\circ} \mathrm{F}$. In use and methods of working vulcanitc and ebonite are practically identical. See Ebonite; Polishing.

WADDING. Cotton wadding, which may be bought cheaply at any draper's, is used for palding such articles as cosies, and also as an interlining for quilting. A layer of wadding, cut to the same dimensions, is laid betwcen the outer fabric and the lining, and the three are quilted together. A special attachment for quilting is sold by sewing machine makers.

Common wadding is usually of a brownish colour. Surgical wadding or cotton should always be employed for wounds or for direct application to the skin, as in making pneumonia jackets. In re-covering chairs it is often advisable to lay a sheet of common wadding inder the embroidered canvas, cloth or leather. See Taxidermy ; Upholstery.
WAFER. A wafer usually takes the form of an initation seal. It is made of glazed paper, gummed at the back, and is affixed to the Hap of the envelope in the saine way as a seal. At one time they were very popular, and were used by many people, but of recent years they only appear in many colours and designs at Christmastime to decorate letters and parcels of gifts. Occasionally wafers are printed for some charitable purpose, and people buy them and use them on their letters as a means of inducing others to subscribe to the charity.
WAFER BISCUIT. Home-made wafers may be composed of equal quantities of sugar and llour moistened with 1 tablespoonful cream and a quarter that quantity of orangeHower water to each oz. of Hour. The mixture is heaten for 3 of an hour and then baked in portions bet ween the wafer irons, somewhat on the same principle as waffles.
An easier and more modern recipe is to beat 1 oz . butter with the white of an egg till mixed, then to add thein to 1 lb . Hour, together with suflicient cream to form all into a thick paste. It is important to knead the mixture till it is as line and smooth as glass; roll out into very thin pieces, shape and hake 3 min . in a quick oven. Before rolling, let the paste stand 20 min .

Waffle lron. An electric waffle iron suitable for table use

WAFFLE. This Amcrican dish is becoming more and more popular in England. It is composed of a thin, rich batter mixture cooked at high temperature in a waffle iron until crisp and brown. A little practice is necessary to achieve the desired degree of crispness, and the amount of batter required for each waffle. The thickness of the batter may vary according to personal taste, a thicker batter requiring a little longer in cooking to crisp it. Plain waffles are served with maple syrup, golden syrup or honey as a rule, or with just a pat of butter on the top.

A good foundation recipe is as follows: 1 heaped breakfastcupful Hour, 2 egg yolks and 3 egg whites, $t$ teaspoonful salt, Iteaspoonful sugar,

WAGES. Money paid for the services of persons in one's employ is known as wages. In the domestic sphere wages are paid to all indoor and outdoor servants, although in the case of governesses and others of superior status the payment is known as salary. IVages are paid either weekly or monthly. There is no rule on the subject, but in general it may be said that indoor servants are paid by the month and outdoor ones by the week. On the other hand, daily maids are as a general rule paid by the week.
Under English and Scottish law employers have certain legal obligations to those to whom they pay wages. The latter must be insured under the national health insurance scheme and against accidents while in the employ of their master. Wages that are not paid when $\frac{1}{2}$ brealifastcupful milk, $\because$ tablespoon fuls melted butter. Sieve the Hour, salt and sugar together, and milk and egg yolks heaten until light, and the melted butter. Beat well, and when smooth add the egg whites bcaten stithy. The batter is lighter if allowed to stand a little time.

Heat the waffle iron, sprinkle with a teaspoonful of water, and when the iron stops steaming put in about a quarter of the waffle inisture. This quantity may vary a little with different irons and only experiment will show the right quautity to use. If too much batter is inserted it will ooze out when the iron is closed; if too little, it will not spread evenly and the thin places will burn. Generally the squares in the iron should be two-thirds full.

Close the iron, and cook until no steam is seen coming from between the two halves. If the waffle is hot, crisp and brown by this time, lower the heat and cook for a minute or so longer, but be careful that it does not burn. Cooking takes 2 to 3 minutes as a rule.

Cheaper wafflcs may be made by using I egg and 2 teaspoonfuls baking powder to the above quantities, while they can be varied by aprinkling the top of the batter when in the iron with chopped cooked sausage or bacon, cooked chicken or grated cheese.

Wamle Iron. This utensil for cooking waffles can be heated by electricity, gas or fire. The electric ones are the most convenient, requiring no turning in the cooking of the waffles, and inany of the $m$ have gauges which show when they are heated to the right degree. They are often made in aluminium or on bright metal stands for table use.
A new waffle iron needs burning in for 10 minutes before use. Then with a soft cloth dipped in melted fat the iron plate into which the batter is poured should be coated thinly with the fat, the iron closed and the heating continued for 3 minutes. It is now ready for use and grease should not again be applied, the surface merely requiring a sprinkle of water.

Wainscot. Fig. 1. Typical oak wainscot. Fig. 2. Showing how a simple wainscot can be made un
from three-ply and battens
due can be recoverd by an action in a court of law, and in the case of an employer going bank rupt unpaid wages must be paid in full before anything is available for the ordinary creditors. See Employers' Liability; Insurance ; Servant.

WAHLENBERGIA. The most beautiful of all the tufted harebells is a little rock garden plant named Wahlenbergia serpyllifolia. It grows only a few inches high and bears large purple blossoms of bellfower shape. It must be ,planted in gritty soil in slight shade. Pamilio has lilac-blue fowers; Hederacea is of creeping growth and bears pale blue flowers. The best method of propagation is by sowing seeds in a pot of fine soil in a frame.
WAINSCOT. The form of wall covering applied to the interior of rooms and known as wainscot or wainscoting is sometimes composed of marble or other materials, but is usually of wood. It takes the form of panelling at the height of about 5 ft . from the Hoor to the top.

In construction, wainscot consists of a series of rails and uprights varying from 1 in . to 2 in . thick, tenoned into each other, the interspaces heing filled with panels from $\frac{3}{8}$ in. to lin. thick. The edges of the rails and uprights are moulded or hevelled; the corners are mitred, and are also grooved to take the panels. Wainscots are generally surmounted by a
capping moulding and finally finished at the bottom with a skirting board.

In oak wainscot it is a common practice to peg the tenons, no glue being applied to the joints. This was the customary method in carly oak wainscoting, in which the lower edges of the rails were left square, the top edges bevelled, and both edges of the uprights moulded. Fig. 1 shows a typical example of a wainscot of oak. Where a very large room is to be fitted, it is made up in sections and the parts secured in position separately.

A cheaper form of wainscot may be made by securing sheets of 3 -ply to a rough groundwork nailed or plugged to the wall, and then nailing a series of battens to the surface to give the effect of panelling. It is essential to arrange the joints in the 3 -ply so that they come opposite the battens, and are thus hidden. The groundwork also should be arranged in a sinilar formation to that of the battens, so that there is a solid ground to nail to. Fig. 2 shows the finished wainscot of this type and the under-ground. An effective finish to the work can be obtained by staining the battens a darker colour than the 3 -ply.

The term wainscot is also applied to oak boards cut in such a way that the silver grain or medullary rays appear on the surface. To secure this effect it is necessary to cut them radially from the centre. See Panclling.
WAITER. This word is occasionally used for a piece of furniture that serves to hold something needful for the table at meal times. Such pieces are usually known as dumb waiters. The word is also employed for a small tray or salver.
WAKE ROBIN. This common name is applied to the cuckoo pint of the hedgerows (Arum maculatum). See Arum Lily: Cuckoo Pint; Trillium.
WALDSTEINIA. This is the name given to a small family of hardy herbaceous perennial plants. known as the barren strawberry. They rarely attain to a height of more than 6 in., with yellow flowers in late spring and early summer. They are propagated by seeds sown at the same period of the year, or by division of the plants in autumn or winter. Waldsteinias flourish in ordinary soil. The most noteworthy kind is W . fragarioides; it is useful for planting on a dry bank.

WALK: In the Garden. For convenience of access to various parts of a garden and to facilitate the work of maintenance it is necessary to have a number of paths. Those of gravel should be not less than 5 ft . wide to allow of two persons walking abreast in comfort. Paved paths, which are more expensive to construct, are usually laid only in certain parts, as in the rosery, the little formal garden or the rock garden ; a width of 3 ft . is sufficient for these. A wide grass path between borders of hardy flowers is very attractive if kept trim. In making a gravel path the soil should be removed to a depth of at least 18 in . and carefully sifted for stones and other refuse. This refuse. together with bricks, broken flower-pots, and other drainage material, should be placed at the bottom of the walk trench, which should then be filled up with coarse gravel and further surfaced with a layer of fine gravel and sand. The whole should be rolled, leaving the centre higher than the sides. Stone or brick paths must be laid on a foundation of sifted soil, sifted ashes, or sand. See Crazy Paving; Path.

WALKING STICK. Sticks have long been used as aids to walking and as a means of defence in case of attack by dogs or men. They are carried, however, by many men merely as an addition to an outdoor outfit, and a present to a man often takes the form of one of these sticks.
There is hardly any limit to the variety in which walking sticks are made. Many woods are used for them, cherry wood and malacca canc being among the most popular, and they can be bought at prices ranging from a few pence to several pounds. The price depends to some extent upon the material, but more upon the mounting, which may be of silver or cven of gold. Initials are sometimes engraved on a band of the metal, this being especially the case with presentation sticks.
As regards shape, sticks may be divided into those with crook handles and those that have no handle but only a finished top. The former are perhaps more useful, and a good example is of imitation ebony with silver mountings at the nose of the crook and at the collar. The best are fitted with a horn ferrule. Of sticks without handles, a good example is

Walk. A richly flowering herbaceous border enhances the beanty of this grass walk, from which, by means of picturesquely curved steps, one descends to a quaint brick path set between grass borders
of cbony fitted with a gold cap. Others are ot malacca cane with a silver cap.
A development of the walking stick is now specially designed for sporting men and women, tourists and walkers, its specia' feature being the addition of a seat. The stick itself has a sharp spike at the bottom so that it can be inserted into the ground, and the seat is made by opening out the handle or head. These sticks are sold in various qualities and designs. The seat may be of mahogany, walnut, or some other wood. The better examples have fittings of aluminium, and the seat is covered with leather. See Ivory.

WALKING TOUR. Persons who spend a holiday, either long or short, in walking from place to place need to observe a few simple precautions if the tour is to be a pleasant onc. Firstly, there is the choice of footwear. Since everything depends on comfortable feet, this deserves a little carc. Stockings or socks should be made of wool, as this is less liable to cause chafing or blisters. Men usually prefer thick ribbed golf stockings.

Boots and Shoes. The boots or shoes should fit well, especially at the heels, but should not be new If they have been in wear for a few weeks they will have taken the shape of the wearer's foot and cause no discomfort. Square heels are essential. The heels should be inspected beforehand and, if necessary, levelled.

People with tender feet are advised to rub them over with a little methylated spirit before starting, and to put a little boracic or other foot powder in their stockings. Some people recommend soaping the inside of the feet of the stockings with a slightly moistened cake of soap. As far as the other clothing is concerned, so long as it is comfortable all requirements are fulfilled, but the wise traveller carries a raincoat or some sort of light coat to put on if the weather changes or during the pauses for lunch, etc.

In arranging a tour, it is wisest to take easy days at the beginning, unless the walkers are in the pink of condition, and to work up for the longer tramps towards the middle of the week, or whatever the period is. It is also wise, when planning the day's distance, to arrange for a shorter distance the day after an extra long one. Fatigue is often felt more the day after than on the day itself.

Accommodation. The securing of accommodation for the night is an important matter. In the more populous parts of the country, where the villages are not very far apart, it is generally possible for travellers to secure sleeping quarters in an inn, or, if that is full, in a cottage near. Many walkers, however, like to walk over more lonely districts, such as Dartmoor, the Yorkshire moors, the Cheviot Hills or the Black Mountains, where houses are few and often at considerable distances from each other. Such persons should arrange the day's walking so that a village or an inn. can be reached before the close of the day. The arrival should not be too late in the evening, so that, if the inn or cottage is full, there is still time and energy to walk a mile or two to another haven.

In 1931 a movement was started to provide hostels for walkers in various parts of the country, and a few were opened during the summer of that year. The idea is to afford shelter for the night at a very low charge. The travellers bring their own blankets and also their food. for which cooking facilities are provided. The movement is directed by a national organization and the opening of a chain of hostels has been planned.
Maps. The walker will find a good map essential. The best are those based on the maps issued by the Ordnance Survey, and the one-inch to a mile will, for the majority, be found the most convenient, although the
two-inch can also be recommended. They can in particular districts. Devonshire cob houses A useful property of many of the wall boards be bought from any stationer. See Holiday. and the stone buildings of Gloucestershire and WALL: In Brick, Concrete or Stone, the northern counties are examples. A A wall is a structure of brick, stone, or other variety of materials have been experimented material, generally built for enclosing a piece with as suitable for walling purposes, notably of ground, or as a shell in which the mixtures of cement and different are formed the rooms of a build ing. There are two main classifications: walls which are built to resist vertical pressure for the support o objects

A

Wall Board. Fif. 1. Sectional diagram illustrating various methods of atilizing the material, in thla case Insulwood, for attic lining, exterior and exterior walls, etc. Wall board forma a roof sheathing, and is laid also under floor boards. See enlarged details of A, B, C. D in Fig. 2
patent Impermeable Millboard Co.. Ltil
placed upon them, such as floors; and those built to withatand oblique thrusts, such as that of a vaulting or untied roof trusses. Another kind of wall for the latter purpose is the retaining wall for earth.
Walls may be hollow or solid, according to the purpose for which they are required. Brick is the material mostly used in their construction except in districts where stone is available. Concrete, too, is much employed. For light partitions and as walls for small buildinge, wood is extensively used the wooden walls being set on concrete or brick foundations.
The thickness of brick, stone, or concrete walls varies according to the weight or pressure they will be called upon to withatand. For walls not more than 8 ft . high, which are to enclose arcas, and will only have to withstand wind pressure, an ordinary 9 in. brick wall should be strong enough; lower walls, not called upon to withstand much weight, could sometimes be $4 \frac{1}{2} \mathrm{in}$. wide, or the width of a single brick. Concrete for this purpose consists of blocks about 18 in . long, 9 in . wide, and $2 \frac{1}{2} \mathrm{in}$. thick

Internal walls may be made up of timber studding and with wall board. They are dealt with under the heading Partition

Rougher kinds of walls, suitable for boun daries, are usually made of random rubble stone. Sometimes a walling material for a small building is simply rammed earth, the muthod being known as pisé de terre. In addition, many other materials are employed
work many different materials are used, including highly compressed paper, wood pulp or fibre rolled into sheets. ply wood, reed and plaster slabs, asbestos cement. Asbestos cement composition is largety used for exteriors and also for interual panelling and partitions. For external walls the material may be purchased with a rough-cast surface on its outer side.

A common size is 8 ft . by 3 or 4 ft . in width. Larger sizea run up to 12 ft . by 4 ft . Thick ness is from $\frac{3}{16}$ in. to $\frac{s}{8} \mathrm{in}$. As the weight is from 8 oz to $l \mathrm{lb}$. per sq. ft., wall board is a good substitute for wood and plaster ceilings, which average about twice the weight of a good quality wall board. Many varieties are supplied with a linished surface to take coating of enamel or paint
For both internal and external walls in bungalows, garages, or other buildings wall board is much used, owing to its panelled appearance and the rapidity with which it can be put up. The drying-off stages of plaster are obviated and an advantage is that the building is fit for habitation immediately upon completion.

Fig. 2. Diagrams abowink varied application ot insulwood. A. 8howing plaster-base applied in sheets before plastering. B. How panelled effect is obtained by using large sheets of wall board. C. Treatment of internal wall, showing use of plaster base. D. Internal wall of internal wall, showing use of plaster base.
covered with wall board and papered

Wall Board. Fig. 3. Snowing now the nome worker can use wall board to partition of a room. The material shown is Essex board Courtesu of Thames Board Mills. Ltd
cutting into a shect of the wall board, the latter may be cut to shape as required with a rross-cut saw. To cut a straight strip from a length of the wall board it thay be heavily scored with a chisel and bent off at the weakened line, the board being supported at the score by placing it against the edge ol a bench. Rough-cast wall board is cut in a similar manner with the score on the smooth side. The rough side is then broken off by continued bending. See Asbestos; Panelling: Partition, Plywooil.
which the panels may be nailed. The framework should be spaced to suit the width of the panel. It must be secured to solid material, and to this end it is best to plug the walls before nailing or screwing on the battens. If the plaster is bulging or broken away, or the surface to be covered is found to be uneven, small packing strips made from odd picces of the wall board may be tacked underneath. It is important, where the wall board is applied to a plastered ceiling, to ascertain that the panel coincides with the joists.
The space between adjacent pancls is covered with an ormamental strip of wood, which gives the panelling effect to this class of work. A convenient size for this strip measures 2 in. wide and $\frac{3}{8}$ in. thick. Before nailing the strip over the wall board the latter should first be painted, taling care that all holes not covered by the parcilling strip arc stopped. In lixing the panelling strips the vertical strips should continue unbrolien if a sense of additional height is required.

A useful application of wall board is in dividing a large room into two smaller ones by nıeans of a partition (Fig. 3). Information about this is given in the article on l'artition. In the event of a window or ventilator

Wall Gardening. An old wall provides an ideal home for pink and mauve aubrietia, slyssum, arabis, silvery saxifrage, pinks and other suitable flowers
blooms in mild weather in autumn and winter, and is in full beauty in spring. Wallulowers are excellent window box plants and will Hourish on a dry stone wall.

The double wallflowers are grown in pots for the deco:ation of the greenbouse in spring. Sceds are sown in a box of soil set iti a frame in Inly and August, the seedlings being potted singly in small pots and subsequently into others 5 in . wide. Some of the walltlowers, e.g. alpinus, light yellow, and Marshallii orange, are pretty plants for the rock garden, where they should be set in light soil in a sunny place.

WALL GARDENING. A dry wal!, that is, a wall built without mortar or cement in the joints, can be made $n$ very beautiful feature of a garden if planted with snapdragon, wall. flower valerian, aubrietia, arabis, yellow

alyssum, silvery saxifrage, pink, sun rose, stonecrop, dwarf phlox, and other suitalle flowers.
If the wall is shady it provides a home for ferns, foxgloves, ivy-leaved tondflax, mossy saxifrage. fumitory, and liellHower. Sceds mixed with a little moist soil may be sown in the chinks of the wall in spring or late summer, or small plants can be set in spring or autumn. A bank provides an excellent site for a dry wall; or a clouble wall may be constructed in the open garden, space being left in the middle for well drained soil. In building a wall care must be taken that it slopes backwards from the base, so that all the plants receive their share of the rainfall.

Fruit Growing on Walls. On a sunny wall it is possible to grow fruits of the highest possible quality. Fan trained or single or double-stemmed cordon trees are most suitable. Planting should be done in autumn in deeply dug ground enriched with basic slag or bonemeal, and it is thenoficial to add old mortar rubble freely to the soil in which stone fruits are to be planted. Care must be taken to set the stems of the trees about 12 in . away from the wall.
A wall facing south or south-west is suitable for peach, nectarine, apricot, fig and the choicest dessert pears. Plums and pears will thrive on a wall facing west. Swect cherries are suitable for an east wall, and on a north wall the Morello cherry and cordon gooseberries and currants may be planted. In cold northern gardens it is worth while planting some of the choice dessert apples against a sunny wall. For a south or south-west wall:
peaches, Hale's Early, L'eregrine, Bellegarde, Barrington and Waterloo; nectarines, Elruge, Hardwicke and Humboldt: pears, Doyenné du Comice, Bergamot d'Esperen. Beurré Superfin, Fondante d'Automne, Glou Morçeau Marguerite Marillat and Winter Nelis: plums, Coe's Golden Drop. Comte d'Althan's Gage Early Transparent Gage, Jeffierson, and Oullin's Golden Gage.
For a west wall the pears and plums already mentioned are suitable. A wall facing east will provide excellent crops of sweet cherries, e.g. May Duke, Black Tartarian, Early Rivers, Frogmore Bigarreau, Kentish Bigarreau. nud Knight's Early Black.

WALLPAPEI. The most important thing to do when wallpapers have to be chosen is to make up one's mind to a definite scheme of treatment. Every room has, by reason of its use, n character which is emphasized by its furnishing and which can be made a ley to the problem of its decoration. Thc personal factor must not be relegated to a sccondary place, hecause decoration should be the expression as well as the environment of personality.
Whatever the purpose of the room, there are certain general considerations which are of importance ; aspect, lighting, size and proportions are conditions which must inHuence choice. Rooms facing north require tints which suggest warmth; south rooms can be treated with schemes in cool colours.
Effect of Lighting. Window space and the conditions imposed by artiticial light should regulate the shade of the wall covering, whether it :s to be light and so capable of refraction, or whether shades which absorb light can lie used. Insufficient light, whether natural or artificial, is a fault which, if it cannot be remedied, must be corrected by the colour and texture of mural coverings if possible.

The effect of light can be attained by ensuring such contrasts of colour and shade as will make objects easily seen which would be otherwise indistinguishable. A wallpaper having a light background with well defined pattern will carry out this idea, or a brightly coloured border having distinctive forms and sharp contrasts will perform the same service.

In this connexion it must be remembered. however, that what is easily seen seems to be near at hand, so that easily seen patterns may appear to reduce the size of a room; whilst, on the other hand. if it is desired to make a room appear larger, indefinite patterns in low tones of colours, tending towards greys, will give the effect of space. The principle might be summed up thus : whatever the eye sees clearly is imagined to be near at hand. whilst haziness and indefiniteness are mentally associated with distance. The apparent size of a room is materially affected by the volume of light which enters it, or is provided by the proximity of the colour of the walls to white. Light and spacinusness are closely related, whilst shade and dark colours suggest cosiness and enclosure. The effect of colour is dealt with in the article under that heading, and that of texture of wall coverings in the article on Decoration.

Use of Pattern Papers. It is not surprising that woven and printed fabrics, embossed leather and other materials which have been used for wall coverings are closely imitated in appearance and texture on wallpapers. There are papers having the appearance of canvas and hessian, produced by printing and embossing, which make excellent wall coverings for rooms which are much used. The designs in popular use in the 18 th century for printed linens and cotton hangings, and the hand worked embroideries which preceded them, have been followed most successfully on wallpapers, and are satisfying for many bedruoms and sitting rooms where the appear-
ance of brightness is desired. There is a series of such papers known as chintz papers, some based on the designs of Qucen Anne embroideries which are most attractive, recalling rooms in country houses with period furniture.
For dining rooms, hall, landings and staircase, patterns hased on tapestry designs have the advantage of traditional associations in their favour, and also of not showing marks. Many are well produced and can be obtained in a wide range of colourings. Soirette is the name given to a type of paper with silky surface which is used for drawing rooms, bedrooms and other rooms where delicate tints are suitable, and the furniture is highly polished and somewhat French in design.

Of the unpatterned papers which are called semi-plains there is sufficient variety in colour, type and texture to suit every kind of room. Here again materials which are used for wall decoration are imitated in wallpaper, notably leather of many kinds, oals and other kinds of wood grain, plaster of rough-cast and trowelled finish. The suitability of this range of papers for particular rooms depends on their colouring and their degree of finish; they are, however. in general use for livingrooms and hall and staircase walls. Effects resembling old parchment are much favoured for modern decorative schemes and other suitable types resemble stippled and mottled paintwork.

The delightful blending of colours found in marbles of many different kinds has given inspiration for a great range of well produced papers in soft tints, but without any attempt at imitative renclering of actual niarble. Others represent marble with varying degrees of accuracy, and these papers are excellent where Regency or Empire effects are liked
Some imitations of marble are popular for bathroome while others are used in narrow widths as surrounds for doorways, windows and niches. Recently there has been a revival of the use of marble papers for staircase and landing walls; when hung horizontally and panelled out to represent slabs the result is impressive.

Motifs and Panels. A form of wallpaper decoration which has become increasingly used within the last few years is achieved by the use of applique motifs which are made in a great number of types and sizes. There are motifs for corners of pancls, pendants for use with cut-out horders, independent

Walnut. Cluster of green-hirsked nuts
ornaments for centres of panels, ovel mantelpieces, bed heads or other positions where attractive colour is desired. All these present little difficulty in arranging. If there should be doubt they can be separated from the surrounding paper, on which they are printed, and pinned up to iudge of their suitability before actually pasting on to the background paper with which they are used. Anotier type of motif is designed for use above skirting or dado rail and takes the form of groups of flowers of varying height and width. Some of these are very extensive, and are of sufficient beight to reach from skirting to picture rail. Their arrangement is not difficult, for with them are generally supplied illustrations showing how they can be adapted. A floral panel and an applied tree motif are illustrated in the article on Decoration.

Corner ornaments are used to enrich panels, which are arranged symmetrically to cover the wall space. Such panels are formed by using a "stile" or "stiling border." These borders are obtainable for use with appliqué motifs, and in several different widths. First the stile is hung under the picture rail and above the skirting, all round the room, then the stile is hung vertically at angles. It there are large wall spaces the stile can be used to form divisions between angles, the lengths being pinned up before pasting so that the proportions of the panels can be adjusted pleasantly.

It should be remembered that these fancy styles of bordered panels look better if one dimension is considerably greater than the other; if both dimensions are nearly equal the effect is not so pleasant. Square panels of this type are uninturesting. Panels in the proportion of 7 ft . high and 5 ft . wide are pleasing, and the narrower the panels in proportion to their height the greater will be the effect in increasing the apparent height of the room. I'anels which are wider than their height will make a room appear lower.

Assistance in connexion with choosing motifs and simulated panelling can be found in the illustrated booklets which are obtainable from most up-to-date decorators. In the article on Hall the attractive use of a landscape motif on a marbled paper is illustrated, and also of a lincrusta panelling. See Colour; Decoration; Frieze: Hall : Panclling: Paperhanging: Paste

WALL PLATE. This phrase is applied generally to almost all types of horizontal timber set upon the top or some other part of a wall to act as a support for joists, rafters, or the like. In a normal two-storey house three principal wall plates might be used. On the ground Hoor, if the floor were made of boarding, the joists would rest upon a horizontal plate of wooll set upon the lower part of the brickwork; this horizontal plate being known as the wall plate.

A somewhat similar arrangement may be adopted for the first-foor joists, except that the wall plate would either he supported on corbels or, preferably, built into the wall itself. On the top of the wall a horizontal member, also known as a wall plate, is provided as a means of fixing the roof rafters and ceiling joists. See Joist : Rafter.

WALL RUE FERN. The popular name of the fern which is known botanically as Asplenium ruta-muraria : it thrives admirably in the crevices of a shady wall. See Fern.

WALNUT. The fruit of the hardy, summerleating walnut tree is a brown nut enclosed in a green husk, and is ripe in September, when it is thrashed off the trees. It is sometimes removed in summer, for pickling. It is best dried after gathering, so that the husks can be removed without staining the shells, and then stored in jars, with salt placed between each layer.

Walnut trees are raised from seed sown in spring and transplanting the seedlings in
autumn, or else by budding or grafting if it is times seen on chairs. The oil polish is far desired to keep a particular form true The superior to a wax finish, as neither heat nor walnut does not thrive in thin soil over chalk or gravel ; it is most successfully grown in a deep loam, with a fairly dry subsoil The walnut produces separate male and female flowers, and the fruit is borne in terminal clusters. After a young tree has been shaped no pruning is required. The common wa!nut is Juglans regia, of which the wood is in demand for furniture making.

Walnuts as Food. In addition to their use as dessert, walnuts are added as ingredients to many dishes that need nut flavouring. Usually they are shelled, peeled, and toasted in a cool oven until they are slightly crisped, and then chopped or broken into small pieces.

One of the simplest ways of using walnuts is to make them into a salad. Toast them and break them up as already directed, having removed the brown skin, and then mix them with some cleaned and shredded celery Only the white portion of the celery should be used, and the quantity should equal that of the nuts. Season the mixture to taste bind it with some thick mayonnaise sauce. and garnish the top with a few halved walnuts. This salad is a good accompaniment to chicken. (See Mayonnaise; Salad.)

Walnut Stains. Of all stains those caused by walnuts are the most difficult to remove On wool or silk they are best left alone, for the drastic treatment needed to take them out is almost certain to ruin the material. On cotton and linen, however, repeated applications of eau-de-javelle or a warm solution of oxalic acid may be effective.

Uses of Walnut. This wood is fairly bard, heavy, and close in grain, easy to work, and does not warp or shrink much. There is the European variety, the best of which grows in Italy; the American black walnut, which is darker in colour; and another American variety called satin walnut. The Italian and American black walnut are those chiefly used for the better class furniture. Satin walnut is used for cheaper furniture, and is not considered a high-class furniture wood. It is soft and tough, and liable to shrink and warp considerably, but is an easy wood to work. It is a light brown or yellowish colour with darker streaks, and shows a satiny surface when planed. The others range in colour from greyish to purplish brown, of ten streaked with darker shades. Walnut is not used by builders, as it often becomes worm-eaten and its durability cannot be depended on.

American black walnut looks very well when treated with a wax polish. The polisher should look carefully for light portions of the wood, and, having found them, should take a small pencil brush and carefully stain them to match the surrounding parts. Some workers use a feather to mottle up the work.

The colouring up of the light portions may be done with a water stain, made by mixing dry powdered vandyke brown with liquid ammonia. and then diluting this mixture to the desired shade; or it may be done with a judicious use of spirit stain, say, walnut crystal, or powdered stain dissolved in methylated spirit. The stain, no matter what variety is used, will raise the grain of the wood, and the usual course of glass-papering down the work must be gone through. Some workers prefer to rub the work over with linseed oil before using a wax polish. If it is tirst oiled in this way, it should stand for at least 48 hours before the wax compound is applied. For chairs, bedroom suites and sideboards waxed walnut is very effective. Some polishers apply a few rubbers of french polish on the top of the wax after it has been allowed to harden.

Another simple way of finishing walnut is by oil polishing. This is generally used for the tops of dining tables, although it is some-
superior to a wax finish, as neither heat nor
moisture will affect it. Wither raw linseed oil or boiled linseed oil can be used American black walnut is frequently french polished. This begins with a preliminary staining, this being done with a water or spirit stain applied to any part of the work that shows signs of light sapwood No hard and fast rule can be given for the mixing. A good plan is to mix a fairly heavy stain, and to dilute it as required.

The next step is to oil the work. Here again colour must be considered. If the general character of the work appears to border on slate colour, it is necessary to use red oil otherwise the work when finished will be dull and lifeless. On the other hand, if the walnut has a rich red shade, raw linseed oil should be used. After the oiling come the three successive processes of filling in, bodying up, and spiriting out. These are described in the article on French Polishing
Walnut Furniture. For articles of furniture walnut was used earlier on the Continent of Europe than it was in England In the latter half of the 17th century it was in great favour in Holland, and, with the close connexion between that country and England that began about 1660 . much walnut furniture was brought over. Ahout the same time the supply of English oak was diminishing, and walnut began to lake its place, the Queen Anne period around 1700 being sometimes known as the age of walnut. In addition to its use for the body of the article, it was much used for veneering, walnut on oak being a popular form. It was employed for decorative furni ture made in the style of Louis XVI, but in England about the same time its place was taken to a large extent by mahogany. In the middle of the 19 th century there was a great revival of walnut furniture, the Italian variety being particularly favoured for fine furniture See Armchair; Bureau; Cabinet; Chair; Dressing Table ; Furniture ; Graining ; Grand father Clock; Inlaying; Marquetry; Mirror Queen Anne Style: Stool: Tallboy: Vencer ing: Wood.

WALNUT BUN. 'The ingredients for making walnut buns are $\frac{1}{2} \mathrm{lb}$. flour, 2 oz . cornflour, 1 teaspoonful baking-powder, 3 eggs, 2 tablespoonfuls milk or cream, a little jam, and 5 oz . each castor sugar, butter and walnut kernels. Put the walnuts into a moderate oven for a few minutes to crisp, and then chop them finely. Cream the butter and sugar, add nearly all the walnuts, then break in the eggs, beating one in well before adding another. Sieve together four, cornHour, and baking-powder, and then add them to the mixture, with the milk.

Beat the whole for a few minutes and put the mixture into small greased tins on a baking sheet. Bake in a good oven until they are firm to the touch. Turn them out and allow them to cool ; then brush them with a little jam and sprinkle with chopped walnuts.

WALNUT CAKE. The ingredients that are required for a plain walnut cake are $\frac{1}{2} \mathrm{lb}$. each butter, castor sugar, and fine flour, 5 eggs , a good pinch of salt, $\& \mathrm{lb}$. peeled and chopped walnuts, and 6 bitter almonds peeled and pounded fine. Cream the butter and sugar till very light, add 2 of the eggs, and beat for 5 min . Add 2 more eggs and beat again for 5 min .; then add the remaining egg and give another good beating to the sponge. Sift the flour with the salt, add the nuts, and mix it very lightly but quickly with the eggs, sugar, and butter.
Put all into a shallow cake tin and bake till firm and a golden brown colour. The time required for baking varies according to the depth of the tin, but the oven must be steady and not too hot.
This walnut cake should be iced with white fondant or French icing. and should be

ady\& Gentleman
Lady\&Gentleman
Waltz. Fig. 1. Steps of the natural turn for both partners. Fig. 2. Those of the reverse turn
decorated with peeled halves of walnuts placerl here and there on the surface of the icing.

A rather nore spongy cake is made without butter. Beat together for 25 min . the yolks of 3 large eggs with 5 oz . castor sugar, adding a few drops of water from time to time, in all 1 tablespoonful, and flavouring with the grated rund of a lemon. Mix with $2 \frac{1}{2} \mathrm{oz}$. ground walnuts, $1 \frac{1}{2}$ oz. wheaten flour sifted with $1 \frac{1}{2} \mathrm{oz}$ potato Hour and a pinch of salt, then whip up the whitcs of the eggs.

Fold the flour and whites of egg alternately into the sponge, putting in about half of each at one time. Bake about 20 min . in a shallow tin lined with greaseproof paper. The oven should be of a moderate heat, and the cake on no account must be moved while baking until it has set. Ice with white icing or merely dust the top of the cake with icing sugar and sprinkle over chopped walnuts. See Cake: Fondant ; Icing.

WALNUT PUDDING. A variety of bread and jam pudding, with walnut flavouring, this can be made in the following way : Heat up 3 gills milk, then pour it over 3 oz . fine breadcrumbs mixed with $1 \frac{1}{2}$ tablespoonfuls castor sugar and a little grated lemon-rind. While these are soaking, shell some walnuts, weigh out 3 oz . of them and toast them for a few minutes before chopping them finely. Then stir them into the bread and milk mixture, adding also the yolks of two eggs. finally mixing in the stiffly whisked whites.
Grease a small pie-dish, put into the bottom of it 1 or 2 tablespoonfuls of jam, then cover the latter with the pudding mixture, and bake it in a moderately hot oven until it is lightly browned.

WALTZ. There are three fundamental steps of this dance, the natural turn, the reverse turn, and the changes, i.c. chanoring from the natural turn to the reverse turn and vice versa. In these three main steps
there is only ono rhythm, a step to every beat. half a turn is made on the first three steps the The music and the steps go in threes, and as man should close his feet together on the the first beat of the music is accentuated, the third step of the reverse instead of crossing first of each three steps should be a little longer them. The same rule, of course, applies to than the second and third. On the third beat the girl's step. Contrary body movement is in both the natural and the reverse turns and used by both dancers on the 1st and 4th steps. the forward changes the feet must be closed toget her.

An important point to observe is the rise, which commences at the end of the first step and continues through the second, bringing the dancer right up on to the balls of the feet on the third step. Contrary body movement (C.B.M.) is used on the first step of every three.

The Natural Turn (Fig 1). This is composed of six steps. In the first three the man steps forward with R.F., turning on it to R., to side with L.F., still turning, and closes R.F. to L.F., completing half a turn. He then steps back with L.F., turning on it to R., to side with R.F., still turning, and closes L.F. up to R.F., completing the whole turn. When the man is doing the first three steps the girl is doing the last three, and vice versa. It is not always necessary to make half a turn on each threc steps, a quarter turn is sometimes used. This depends on the direction in which the man wishes to steer. Contrary body movement is used on the lst and 4th steps by both man and girl.

The Reverse Turn (Fig. 2). In the first three steps the man steps forward with L.F. turning on it to L., to side with R.F., still turning, and crosses L.F. up in front of R.F. completing half a turn. He then steps back with R.F., turning on it to L., to side with L.F., still turning, and closes R.F. up to L.F., completing the whole turn. When the man is doing the first three steps the girl is doing the last three, and vice versa. As in the natura turn, it is not always necessary to make half a turn on each three steps; but if less than

The Forward Changes (Flgs. 3 and 4) 1. After a natural turn the man steps forward with R.F., turning body slightly to R. (C.B.M.), to side with L.F., and closes R.F up to L.F. The girl steps back with L.F., turning body slightly to R. (C.B.M.), to side with R.F., and closes L.F. up to R.F. 2. After a reverse turn the man steps forward with L.F., turning body slightly to L. (C.B.M.), to side with R.F., and closes L.F. up to R.F. The girl steps back with R.F., turning body slightly to left (C.B.M.), to side with L.F., and closes R.F. up to L.F.
The Backward Changes (Figs. 5 and 6). 1. After the first three steps of his natural turn (1, 2, 3, Fig. 5) the man steps back with L.F., turning body slightly to R. (C.B.M.). back with R.F., back with L.F., only just passing R.F., and finishes with the last threc steps of his reverse turn. The girl, after the first thrce steps of her natural turn, steps forward with R.F., turning body slightly to R. (C.B.M.), forward with L.F., forward with R.F., only just passing L.F., and finishes with the last three steps of her reverse turn. 2. After the first three steps of his reverse (1, 2, 3, Fig. 6), the man steps back with R.F., turning body slightly to left (C.B.M.), back with L.F., back with R.F., only just passing the L.F., and finishes with the last three steps of his natural turn. The girl commences with the first three steps of her reverse turn, steps forward with L.F., turning body slightly to L. (C.B.M.), forward with R.F., forward with L.F., only just passing R.F., and finishes with the last three steps of her natural turn. In the diagrams accom-
panying this article the right foot is shaded but the left is shown in outline only. The dotted line indicates the ultimate position of foot. It will be easier to follow the diagrams which are given in this and the previous page if the dancer faces the direction in which the toes are pointing and turns the diagram at the same time. See Dancing; Fox Trot Quickstep; Tango.

WARD: In Chancery. By the theory of English law the king is the guardian of every infant (i.e. person under 21) in the country, but he exercises this guardianship through his judges, and only becomes an active guardian when in some way an infant is brought before the court. Any person under 21 may be made a ward of court by someone paying into court a sum of money in which the infant is declared to be interested. The court will not usually interfere unless the infant has some property.

The position of such a ward is that he or she cannot marry without the consent of the court. It is a contempt of court punishable by imprisonment for anyone to marry such a ward without the judge's leave. Ignorance that the infant was a ward of court is no defence in a case of this kind

The judge has power to order the infant to be placed in the custody of any person he chooses. He can even take a child out of the custody of one or both of its parents and hand it over to somebody who may or may not be a relative.

The National Society for the Prevention of Cruelty to Children uses this weapon sometimes in order to take children out of the custody of undesirable parents. It is contempt of court for anyone to interfere with such custody or to remove the infant out of the jurisdiction of the court without leave. The wardship ceases when the infant attains the age of 21. See Guardian.

Waltz. Diagram showing the various steps and turns. Figs. 3 and 4 show the detaila of the forward change. Figs. 5 and 8 . The backward change

## Wardrobes: Antique and Modern

With Designs for a Hall Wardrobe and One in Veneered Walnut
After some remarks on the story of this piece of furniture, this contribution pives particulars, aided by diagrams, about making two types of wardrobe. The worker will obtain further assistance by consulting the entries Cabinet Making; Joint; Polishing; Stain; and others on woodworining processes. See also Bedroom; Corner Wardrobe: Cupboard; Fur; Furniture; Hall

The wardrove was evolved about the last panelled: and helow were two small drawer: decade of the 17 th century from the hanging and two larger ones. Contemporary wardrobes cupboard and is a combination of that piece and a chest of drawers. Examples of Queen Anne period pieces are rare, but there is an intercsting child's wardrobe dated 1712 in the Victoria and Albert Museum. It is made in the form of a contemporary house. painted to resemble brickwork. The roof has a gable at either end. a hexagonal chinney and dormer windows. There are three rows of sash windows across the front. The doorway has pilasters and curved steps.

The centre of the front is hinged and forms the door of the cuphoard fitted with clothes pegs. There are two wings, one fitted with small drawers and the other with shelves. It is therefore a complete wardrobe in the modern sense

A hout the middle of the 18 th century a higher standard of comfort was introduced into bedroom furnishing, and accommodation for clothes improved from the usual tallhoy to the clothes press and wardrobe. The clothes press is sometimes known as a " gentleman's wardrobe." It consists of a cupboard enclosing sliding trays and mounted on a low chest of drawers. Most of these pieces were made of plain mahogany, but highly decorative carved pieces were based on a design in Chippendale's "Director."

Hepplewhite also designed and made wardrobes. In one fine example the mahogany piece was inlaid and ornamented with marquetry. The upper part was the wardrobe proper, enclosed by two doors. which were
were of paintcd or lacquered rood. The illus-
tration shows a bcautiful piece with a Chinese design in lacquer work made for Javid Garrick.

Sheraton's designs for wardrohes were usually of mahogany with restrained use of inlay or marquetry in satinwood. The Regency period wardrobes by first-class makers often showed the familiar association of strongly figured woods with brass mountings. By the middle of the 19th century mahogany and walnut wardrobes had reached heavy and vast proportions, and a little later the wardrobe hecame part of a bedroon suite, including also a washstand and dressing table. Such wardrohes usually have a mirror on one side. in the centre, or inside the cupboard door.

Modern Wardrobes. Apart from pieces included in modern suites, which are to be had in mahogany, weathered oak, Jacobean oak, walnut, sycamore and enamelled or painted wood, wardrobes in recent years have again been made as separate pieces either of the compact fitted type or designed to suit a special room. A good example planned for a man's study-bedroom looks like a sidehoard-hookcase, but when open the two sides reveal a wardrobe fitment. The size of the hanging cupboard section is sufficiently large to take a number of a man's suits on hangers and is provided with a sliding rod. The other wardrohe section contains shelves and drawers. The central portion is reserved for hookshelves.

The compact fitted wardrohes are usually in oak or mahogany and are made in three or foum sections. Some de signed particularly for men are provided with hanging space, sliding trays, shelves, an ex tending fitment on which to hang trousers. hootrack and a mirror. Other compact ward rohes are specially de signed for women with more hanging space and good shoe and hat accommodation. The fashion for huilt-in furniture has extended to wardrobes. The illus. tration here shows one provided with an electric light which goes on when the door is opened and out after the required garment has been selected and the door is closed.

Quite an excellent wardrobe can be made of two whitewood cup. boards, a narrow and a medium-sized one, screwed together to make one piece of furniture and painted or stained to match the walls or wood work of the room. The wardrote is provided with brass rods for the accommodation of hangers. One rupboard is used for heavy coats, the other being reserved for light dresses, etc. Alter
natively the narrow cupboard may the fitted with trays or shelves. Ornamental brass drops or ring handles if the wardrole is stained, or if painted china or coloured glass knobs, and a lining of glazed chintz linish the piece The lining is attached with drawing pins, a curtain gimp hiding the edges and being caught down with invisible gimp pins.

Making a Wardrobe. The amateur who is desirous of constructing a wardrobe will find it worth while to study such woodworking articles as Cabinet Making: Cupboard. retc. Some proficien y in the use of tools and the making of the principal joints should be acquired before attempting a joh such as the hall wardrohe or the veneered walnut article later described. If just a simple piece of furniture is needed which entails the minimum of skill and experience, the cuphoard illustrated on page 325 could be modified slightly to serve as a hanging wardrobe. By incorporating a contre vertical partition and fitting the usual shelves, trays and pigeon holes to one compartment a useful man's wardrobe might be built.
On the opposite side $n$ shelf for hats at the top and a rail for hoots and shoes at the

Built-in wardrobe with electric light fitted to switch on with the opening of the door. The light is switched off when the door is closed
hottoin could be contrived, laving the resi of this compartment for coats and suits, supported on hangers which liook on to a sliding litting attached to the under side of the hat shelf. A small mirror in a frame can be serewed to the back of one of the doors. The necessary metal fittings can be purchased at an ironmonger's.
Hall Wardrobe in Oak. A length of 30 in for a hall wardrohe is ample for the small hall. It enables a good many coats to be put away, and does not take up much space The wardrobe in Fig. I is intended to be made in oak. Practically the whole thing can be made up from $\frac{z}{8} \mathrm{in}$. oak for the main framework, and is in. oak-veneered plywood. It is possible to obtain ready grooved oak, the advantage of the use of whinh is that it saves the somewhat awliward job of grooving. If one has a grooving plane there is no difficulty, but this is not a tool genera!!y found in the amateur's
 oincide by fixing the joining parts tog with a cramp and squaring lines across with a pencil. Then set a marking gauge and mark each line. Dowels $\frac{3}{8}$ in. thick are suitable. Cramps should be used after jointing up, so as to draw the parts tightly together
centre. It is nccessary to stop the chamfer on means of dowels let into the edges of the sides the bottom rail at the centre where the up-
(Fig. 3). In order to make good joints the right joins it. This is shown clearly in Fig. $\tilde{0}$. sides should be carefully planed and fitted A moulding. similar to that on the top. rail against the front and back. It is at simple is worked at both edges of the centre upright. The diamond decoration in the top pane is formed by the application of a thin fret with a moulding mitred round the edges. Wrought iron hinges screwed direct to the surface are the most suitable to use. A good finish for the job is a dark oak stain followed by one or two coats of french polish. After
this the surface can be well
 waxed.
Veneered Walnut Wardrobe. Present day design favours the use of large unbroken surfaces in which the work relies for its effect upon the main proportions and upon

Wardrobe. Small wardrobe for use in a hall. Fig. 1. Completed wardrobe. Figs. 2 and 3 . Working details, together with method of construction

For the top a piece of plain plywood can be the beauty of the material. The wardrobe used. If it is intended to use extending hanger shown in Fig 6 exemplifies this tendency. The rods a piece of solid wood should be attached doors have no visible framework, the whole beneath it to provide a fixing for the screws. surface being flat. The decorative effect is Fig. 4 shows how the bottom rests upon produced by the use of choice veneers. fillets fixed to the rails. The addition of the Another feature typical of modern practice cornice moulding completes the main carcass. This is mitred at the carcass. This is mitred at be added if desired.
Making the Door. Fig. 5 shows how the door is made. The framework is put together with mortise and tenon joints and the inner edges are grooved to hold the panels. A decorative effect is produced by moulding and chamfering the edges. The top rail is moulded at its lower edge. The middle rail is cham. fered at the top and has a channel worked along tbe

rests upon fillets ${ }^{n}$ red to the rails. Fig. 5. How the door is made
is the absence of a cornice. The doors run right through to the top and are shaped.
The wardrobe gives excellent accommodation. There are three main cupboards, and these can be fitted up in any way the worker pleases. It is advisable to give over one entirely to hanging space, with possibly a boot rack at the bottom. The other two can be arranged to have shelves or drawers as desired. For the main sizes see Fig. 7. Fig. 8 shows how the main parts are made. There are three separate carcasses for the cupboards and a plinth upon which these stand. Each of these four parts is made up as a complete unit. Yellow pine, mahogany, or some other wood suitable to take veneer should be used throughout.
The Carcass. The sides of the centre carcass stand forward beyond the others. The reason is that the centre door must be contained between them, for otherwise it would be impossible to hinge it. The side doors are hinged over their carcasses. In order that the crossbanded effect on the doors may be continued

thickness of the back before being fixed to the framework. Note ${ }^{\circ}$ ( $\frac{7}{8} \mathrm{in}$.). Rebates of that the top rails must be sufficiently wide to" this depth are worked allow for the shape to be worked in them. in the back edges of the sides to hold the back. This is also true of the centre carcass, but the top and bottom are made narrower still because the door, although it is contained between the sides, closes over the top and bottom.

When the carcasses have been glued up and tested for squareness the backs can be made. These are plain frames mortised together and with grooved-in panels. They are screwed on. If permanent shelves are being introduced these can be either housed in or be sup. ported by fillets. If the former method is adopted the housings should be worked before the carcasses are assembled. It is not practicable to use fillets in the case of drawers, and the rails for them must be housed in.

The Plinth. At this stage the plinth should be made up. Its con round, the front edges of the centre sides are struction is shown in Fig. 8. It consists of cross-banded. In this way they appear to be part of the doors themselves.

No attempt is made to follow the top shaping of the doors in the carcasses, except that the centre carcass is taller than the others and lines up with the over-all height of the side doors. One important point to watch in making this job is that all three carcasses must be made perfectly square. Otherwise, when they are assembled they will not stand true on the plinth, which is, of course, straight.

Lap-dovetails are used in the construction of the carcasses, as shown in Fig. 8. Dealing first with those at the sides, note that the top and bottom are narrower than the sides by the

Working diagrams of the wardrobe illustrated above. Fig. 7. Details of the main measurenents. Fig. 8. How the principal parts are assembled. Fig. 9. Simple method employed for constructing the four stout stub feet into which the rails are tenoned. As it has to support a fair weight 11 in . stuff should be used for the rails. To give additional strength two intermediate rails are dovetailed in between the front and back rails.

After glueing up the joints are levelled and the surface veneered, the grain of the veneer running vertically. A wide, flat moulding is planted on top. Glue blocks should be rubbed in at the angles to reinforce the whole.

A simple method of making the doors is given in Fig. 9. A main framework of $\frac{s}{2}$ in. stuff is made up and a plywood panel glued over the front. The panel should be veneered -
them, provided this took place after they had passed into its keeping.
The charges for warehousing should be paid. when due. If they are allowed to fall into arrears and the arrears become considerable, the warehousing firm may sell the furniture to discharge the debt owing to it. Before doing this, however, ample notice should be given to the owner, or, if he cannot be found, the intention to sell the goods should be announced in the daily papers. The warehousing firm may also refuse to part with the furniture until all its charges bave been paid.

Certain articles, such as pianos, are sometimes warehoused separately from other articles. Most dealers in musical instruments store pianos, and the arrangements for this are practically the same as for other articles of furniture. The storing firm usually undertakes to tune the piano at regular intervals. See Removal.

WARMING PAN. The predecessor of the india-rubber and stoneware hot water bottles was the warming pan, a shallow. circular vessel with a hinged lid, made of stout sheets of copper or brass. It was filled nightly during the cold season with redhot coals and placed inside the bed. It was provided with a long handle, occasionally of iron, but generally of polished wood turned in the lathe. To avoid creasing the sheets, the top, bottom, and sides were made slightly convex in form.

Warming pans were in usc from the 17th century onward. Early examples often bear a date engraved or embossed on the lid, sometimes with homely proverbs, pious mottoes, or loyal sentiments, such as one dated 1622 which reads " God Save King James." These appliances are now in request by lovers of old brass, and they have not escaped the attention of the counterfeiter. They may be kept bright with dry leathers, preferably without metal pastes, and should not be lacquered.

WARRANT : In Law. A warrant is a direction under the common seal of a competent court or magistrate directed to an officer ordering or authorizing him either to seize the property of a debtor or offender, to arrest an offender, or to search a certain place or the actual effects of a certain person.

Warrants for arrest can only be issued by magistrates on sworn information, and will only be issued in the case of serious offences where it may be supposed that the person charged is about to attempt to escape or might run away if only a summons were served upon him. The difference between a warrant and a summons is that a summons is a document that is sent to the offender ordering him to attend the court on a certain day to answer a charge, while a warrant is directed to a police officer ordering him to arrest the offender.

A search warrant is only granted on sworn information and on strong grounds. It is very often applied for in cases of breaches of the liquor licence law. If a mistress wishes to search a servant's box on guspicion of theft, her only legal course is to obtain a warrant and have the search carried out by a police officer.

A prosecutor who goes to a magistrate and gives

Warming Pan in embossed brass Courtesy of Country Homes Supplies
him information, even though it be false, upon which a warrant is issued by the magistrate is not liable in an action for false imprisonment if the charge turns out to be a false one, though he may be liable in an action for malicious prosecution. Any police officer who arrests an alleged offender without a warrant is not liable to an action for false imprisonment if he can prove he had reasonable cause for suspecting that a felony had been committed and that the person arrested had committed it, or that he made the arrest to prevent a breach of the peace.

A private person, on the other hand, who arrests a suspect without a warrant must be prepared to prove that a felony actually had been committed, and that he had reasonable grounds for suspecting that the person whom he arrested had committed it. See Summons.
WART : How to Cure. A wart is a simple growth consisting of over-developed skin papillae. Warts occur most commonly in young people, on the hands, feet, and scalp. They are contagious.

Warts can generally be treated by applying glacial acetic acid every two or three days. This can be done with the end of a match. Care should be talken to keep the acid off the surrounding skin as much as possible. When warts are large in number and widely distributed, the free use of lime water inwardly has been said to be beneficial.
Care should be taken in applying caustics to warts in elderly people, especially those occurring about the face, as the growth may readily become malignant. The so-called butcher's wart is a local infection with tuberculosis.

WART DISEASE. This disease, which is known also as black scab, has been the cause of immense loss to potato growers : the warts, which form in the "eyes" of the potatocs, develop into small, cauliflower-like growths, eventually the whole tuber decays and the soil becomes infccted with disease spores.
Fortunately the introduction of a race of potatoes which are immune to wart disease has been raised; these may be planted even on infected land. Some of the best potatoes which are immune to the wart disease are (early) Witch Hill, Immune Ashleaf, and Di-Vernon, (Second early) Arran Comrade, Ben Lomond, Abundance, King Gcorge, Arran Banner. and Great Scot. (Maincrop) Ben Cruachan, White City, Arran Consul, The Bishop, and Golden Wonder. Popular varicties of potato which are liable to attack by the wart discase and must not therefore be planted on infected land are King Edward, Duke of York, Sharpe's Express, British Queen, Arran Chief, and Up to Date.
WASHER : For Clothes. Where a good deal of laundry work is done at home, the task is simplified by the use of a reliable clothes washer. These machines are classed as gas, non-gas or electric washers. The gas models are provided with a gas burner, a heat retaining outer cover and constructed with a copper tank. Models are also obtainable which are complete with wringers and table tops. Deferred terms can be arranged for British washers which are fully guaranteed.
There is no complicated mechanism, and in most washers the agitator produces the actions of hand washing by means of which fabrics are stirred, squeezed and rubbed. Emibedded dirt is removed by the vigorous swirling of the agitator. A gas model is reckoned to consume about 3d. gas in an hour and to use half a bar of soap in doing the washing for a
family of several persons. Some electric models are stated to cost only ld. an hour to un.
A vacuum electric washer has no moving part. The soapy water is drawn through the weave of the fabric fifty times a minute by

Washer for Clothes. Complete with wringer, this wasber takes up little room, and fits into the legs when not in use Press Caps. Ltd.
the bubble action of the vacuum washer. A tablespoonful of soap flakes are placed in the bottom of the washer tub, the clothes are dropped in and the tub filled with water. The unit cylinder is then dropped into place and the machine is plugged to the nearest electric outlet for 20 minutes. The soapy water is then poured away and the clothes rinsed in a similar manner to that of the washing operation, but only immersed for a few minutcs. See Laundry.

Washing. See Laundry.
WASHING. In Photography. The importance of washing thoroughly all plates, films, and prints cannot bc too strongly emphasized. Prints or negatives which are insufficiently washed will inevitably develop stains and spots, or else the prints, particularly if made on gelatino-chloride paper, will gradually fade until the image disappcars altogether. As many prints and negatives are spoiled by insufficient washing as by any other amateur fault. The object of washing is to remove all traces of hypo (sodium hyposulphite) and free silver.

By thorough washing is not meant prolonged washing. It is quite possible to wash a print in a deep dish, from which the water overflows only at the top, for 10 to 12 hours, and still find traces of hypo. The reason is that hypo solution is heavier than plain water, and sinks to the bottom. Although various hypo eliminators have been recommended from

Wesbing in Paotography. Fig. 1. Wasting tank 10 r plates. It is in japanned tin and fted with a syphon

Washing: in photography.
Fig. 2. Excellent type of washing tank
timeto time there is no doubt that water, pro perly used, sup. plies the quickest and best means of removing hypo. Experiment has shown that 10 min . really efficient washing is sufficient.
The amateur must not imagine that he will be safe if he washes his plates or prints in a sink or bath under a stream of running water for so short a period as 10 min . The most efficient method, though rather tedious, is to immerse the negative or print in a dish in successive changes of water. The print is a!lowed to stay in the water for 7 or 8 min., the dish rinsed out and then filled again with fresh water. If this is repeated eight times the most delicate chemical test will reveal no trace of hypo.

Apart from the use of the commercially inade washing apparatus, several methods are open to the amateur photographer. The points to bear in mind are that the water must always be able to run away from underneatle; that the water must have free access to both sides of roll films, and these must not be allowed to curl up or to get into violent motion which would cause scratches and other damage; that prints should not be allowed to stick together: and, finally, that postcards and prints on thick paper must be washed for a considerably longer time than other prints, since the hypo is present in the pores of the paper as well as in the film. In practice, if the washing methods are sound, the following times will be sufficient:

Glass plates and bromide and gaslight prints on light-weight paper, $\frac{1}{2}$ hour. Roll films and ordinary P.O.P. prints, $\frac{3}{4}$ hour. P.O.P. postcards and heavy-weight prints, one hour. These times will allow a certain margin of safety.
Glass plates may be placed in a clean sink

Fig. 5. Print washer so shaped that, on connecting it to a tap with rubber tubing, the water and the prints are lept in a circular motion Courtesi" of W. Butcher it Sons. LId.
under a gently Howing tap, if means are adopted to prevent them being washed over and blocking up the outlet, so causing the sink to fill and overflow. Adjust the flow of water so that all the plates are sufficiently covered with out the stream being so violent as to move them about. Flat films and prints may be washed in a bath with the waste plug nearly closed and the inflow regulated so that the water level remains constant. Each tilm or print is Hoated by means of a cork in which a nick has been cut with a sharp knife, the corner of the print being inserted in the nick. A large cork can be cut up into a number of slices about $\frac{1}{\frac{1}{2}} \mathrm{in}$. thick, each slice being nicked. The water flow will keep the prints on the move, while the corks prevent them sticking.
Roll films can be washed by a similar method if larger picees of cork are attached at both ends, at one corner and also one or two others along the edge, so that the film is suspended edge downward in the water, while the cork prevents it rolling up. Any risk of damage to the surface of the film while wet is avoided by the use of wooden spring clips to which the corks are attached.
Washing tanks for plates in japanned tin or zinc can be obtained in various forms. A simple form is shown in Fig. I, which holds 12 quarter plates or 6 half plates. It is fitted with a syphon so that the water is removed from the bottom of the tank. A better form is shown in Fig. 2. Herc a complete change of water is obtaincd every minute. The principle is seen in the diagrams Figs. 3 and 4.
An effective print washer is illustrated in Fig. 5. It is connected to the tap by a short length of rubber tubing and so shaped that the water is constantly in a circular motion,

Figs. 3 and 4. Sectional view of tank shown in Fig. 2. Left, syphon shown in full action, hypo laden water (coloured dark greg) being removed, and fresh water (coloured light grey) taken in. Right, when water level reaches bottom of inverted cone on inlet of syphon tube, a hole admits air to syphon and stops water discharging. The whole process is then repeated
ourtcs" of $w$ Rutcher \& Sons. Ltd.
carrying the prints with it. This washer can be obtained with a metal rack to take plates.

Where a considerable number of prints have to be washed, special types of washer can be obtained in which the large numbers of prints are kept in constant rotation by means of apparatus resembling a turbine.

A simple test for the presence of hypo, whicb will indicate whether washing is efficient, is applied by allowing the last drips from the negative or print to fall into a tumbler and adding a little water faintly tinted pink with potassium permanganate. If hypo is present the pink tint will disappear immediately. See Bromide Paper: Fixing: Negative; P.O.P.: Printing.

WASHING POWDER. For washing clothes and other domestic purposes special soap preparations are sold in the form of powders. As some are injurious to fine materials only those produced by reliable firms should be used, and the powder should be dissolved in the washing water before the clothes are put in. Washing powders will make a quick lather, and arc less wasteful than soap. They may be employed also for dish-washing, and are more satisfactory than solid soap for use with washing machines. Sce Laundry : Soap.

## WASHING-UP IN THE HOME <br> How Modern Methods Lighten this Domestic Labour

This article gives useful bints on the daity elcansing of china, glass, and silverware, and also of cooking utensils. Other entries that mav be consulted are Aluminium; Draining Board; Hot Water Supply; Kitchen; Scul!ery; Sink; Water

There are many devices for lessening the
udgery of washing up after meals and drudgery of washing up after meals and cookery. The most expensive is a dish washing larger household the former appliance is probably worth while. A combined clothes and dish washer is obtainable in three models, hot water, gas and electric, and converted from one of its cleansing uses to the other by the simple interchange of two fittings The floor space required is 20 sq . in. : the machine washes and dries all classes of crockery. There are several other types of washing-up machines on the market, the general principle of these being that hot water is sprayed on to the plates, etc., and when the hot water is turned off they are dried by hot air.
Apart from such a machine, the task of washing-up is made less fatiguing by the use of plate racks, draining boards, and various othet devices A plate rack fixed over the sink or draining board does away with the necessity of drying plates and dishes. provided they are thoroughly rinsed An improved type of rack is made to hold cups and tumblers in addition to plates Some are made so that they can either hang on the wall or stand on the drain-
ing board. Sinks should, when newly installed, be placed in a good light and at a convenient. height to obviate stooping too much while working. Where an existing sink is too low, boards made of wooden slats raise the height of the washing-up basin.

Portable draining boards are made to clip and clamp on the side of the sink. These are useful in sculleries where the sink is immediately next to the door or passage-way, and where a fixed board is not possible.

Inexpensive Aids. Papier mâché or wood pulp bowls are more suitable than those of metal for washing up glass and china, as they save a number of pieces from chipping and breakage during the year. A long-handled mop saves the hands. A plate scraper should be used to remove particles of food and grease from dishes, etc., before putting them into the water. A little pad is obtainable for cleansing and polishing knives.

Bottle brushes are invaluable for decanters and other narrow-necked vessels, whilst fresb tea leaves may be used to remove stains from the inside. A spiral rubber mop can be obtained which is excellent for cleansing glass bottles. Wire-headed brush mops are useful.
for detaching particles and grease from saucepans, while a scouring glove and a metal acouring pad are both practical aids for the same purpose.

The cleansing of greasy articles is greatly assisted by the use of soap or soap powder in the water, so as to provide a lather The small pieces of soap that accumulate in a house can be utilized in this way by being put into a wire soap saver. The oddments are placed in the cage of this and boiling water poured on to them, a few whisks with the soap saver quickly producing a lather. To soften the water and to save soap, a little washing soda emulsifies grease and makes it easy to remove. Those who find that soda has a barsh effect on the hands and causes cracks should put a tablespoonful of borax instead of the soda in a medium-sized basin of water. Rubber gloves are suitable in cold weather for anyone whose hands quickly chap and crack. If the insides of the gloves are sprinkled with French chalk before use they do not stick to the hands

Efficient Procedure. Whether the washing $u_{p}$ is done by band or machine, plenty of hot water must be available This is an important matter to be seen to when moving into a new bome For a small anount of washing-up a kettle or large saucepan can be boiled In a gas oven, after the gas is turned out, there is usually sufficient heat retained in the oven to beat a basinful of water ; if it is not quite hot enough a few minutes over a small gas. ring will bring it to the right temperature.

Where there is no constant supply of hot water from the range or from an indejendent boiler, a supply is obtainable at a minimum cost by the use of a small gas or electric water beater placed near the sink In districts where electricity or gns is not available, a rapid water heater may be installed for use with paraftin oil or an oil stove will supply sufficient bot water.
When the washing up is actually done in the sink or in a basin standing in the sink, the right-hand draining board or a small table placed against the right side of the sink is the most handy position for the dirty things Where there is a pantry, finer china, silver and glass ware will be washed at the sink there, the cooking utensils and crockery, etc.. being done in the kitchen.

First remove all scraps. remains of food, and grease from plates, spoons, knives, and forks-a picce of newspaper can be used for the purpose if no scraper or rubber squeegee is at hand. Tea cups and milk glasses should be rinsed under the cold tap. If a little trouble is taken with this part of the work the washingup water will remain comparatively clean

The things abould be wrshed in the following order: Glass, silver, china, knives and other metal articles, saucepans, and baking tins. A few things only shonld be washed at a time, and, when there is a good supply of hot water, a better result is obtained and with less effort if the things are rinsed in hot water. drained, and dried at once. The smeary marks frequently noticed on glass and chinn are due to the fact that water containing soap and soda bas heen allowed to dry on the articles instcad of being removed with a cloth or by rinsing.

When washing china with gilt or hand colouring on it, soda or strong soap powders should not be put in the washing-up water, as the alkali is likely to remove the gilt and spoil the colours. Glass requires special care, particularly when new. The water should not be very hot or the glass cracks, being a poor conductor of heat, and the thicker the glass the more liable it is to fly. A small brush should be used to clean cut and moulded glass.
White marks on water jugs and bottles are often caused by hard water that cannot be removed with soap and water. The best way to deal with these is to allow vinegar to re. main in contact with the chalky deposit for a
short time, then rub hard with a small piece on the same lines as a !avatory basin, in more of cloth moistened in vinegar : the acid in the vinegar dissolves the chalk A rub with a cut lemon answers equally well.

All knives and forks with handles attached require special care. Wbether the handles are riveted or stuck on, they should on no account be put right into the washing-up water, for hot water soon loosens those that are stuck on and cracks and splits ivory. They are best placed upright in a jar or jug partially filled with hot softencd water

To simplify the cleaning of greasy saucepans and baking tins, till them with warm or cold water immediately the contents have been dished up, add some washing soda, stand them on the stove or in the oven, and when ready to be washed the pans will be found to be practically clean All sauccpans, other than aluminium, in which food has been burnt should be boiled up with a strong yolution of soda and allowed to soak, as this saves both the time and labour necessary for hard scouring.

After use, the washing-up bowl mop, dishl cloth. scouring cloth, or saucepan brush shou!d be scalded, and then washed in hot soapy water, rinsed, and hung up. Separate towels are required for drying glass, china. and silver and knives. So that they may be easily distinguished; the glass cloth could be of checked linen of medium texture, the china clotlı of coarse white linen. and for knives and tins a thick, unbleached linen towel is suitable.

WASH LEATHER. Wash leather or chamois lcather is unrivalled as a cleaner and polisher of glass and silver. It should never be used with anything but cold or tepid water: hot water will cook the fibre and render it perished and brittle. After use, the surplus moisture should be wrung out and the leather hung to dry. When thoroughly dry it will be found somewhat hard, but can be returned to its original softness by pulling and stretching.

Wash leather should always be used in preference to other materials for putting the finish on silver and plated articles, after all plate powder or whiting

Wasp. Enlarged pnotograph ol tols stinging summer insect less expensive styles, and provided wit pedestal base or supported on plated legs.
Antique mahogany washstands of corner shape are usually more decorative than practical. Many people cover the top with a fitted board, hiding this with a shaped piece of old brocade, damask or tapestry needlework, and thus convert the washstand into an attractive little corner piece for the sittingroom. Sec Bathroom: Bedroom.
WASP. Usually in hot weather numbers of these insects frequently invade the house, especially congregating where there is anything sweet, such as jam or fruit. They are not only a great nuisance, but, owing to their capacity for slinging, may be a positive danger They can be killed one by one, or trapped and then killed, but a better plan, if it is possible is to seck out and destroy their nest.

Treating a Sting. When a person is stung by a wasp, the part begins to swell almost betore the first acute pain from the wound subsides. This swelling is generally confined to the immediate neighlourhood of the point of entrance of the sting.

Ordinarily the system is not appreciably affected by the poison in the sting, but in rare cases, and particularly when the victim has been stung in a number of different places, the poison may act directly on the heart. A wasp sting over a vein, where the poison is poured directly into the blood stream and so carried straight to the heart, is more likely to be serious than one in which the poison enters solid tissucs underlying the skin.

A wasp sting on the tongue, lips, or inside the cheek may lead to sulfocation through rapid swelling of throat tissucs, preventing air being drawn into the lungs. Not itrfrequently, as the result of the wasp poison in the blood, a type of nettlerash, which may persist for several days, may break out over the part affected. In some cases this rash may cover the whole body.

The wound should first be carcfully examined to sce whether the insect's sting has been left behind. If so, this should be care- fully squeezed out or rewill not only impart a high polish, but its moved with a necdle or a fine pair of continued use will remove light surface tweczers. If the pain and swelling are severe, scratches. The best results nre obtained by a bandlkerchief soaked in lead-water and the aid of a small quantity of jeweller's rouge laudanum lotion may be lightly bandaged applicd as a final operation with soft, dry wash Icather.
Grease marks and other stains on articles made of suede leather or cloth with a ve!vety pile or nap, soft felt hats, for instance, may be removed by rubbing briskly with a clean, dry picce of wash leather. The linings of men's pockets, especially vest pockets, are sometimes made of wash leather. See Glove: Window.
W ASHSTAND. Except in houses where the bathroom accommodation is limited for the number of bedrooms, or in rural districts where the water supply has to be coonomically considered, there is a tendency towards the disappearance of the movable washstand as a piece of furniturc. They can be bought separately or made to match other bedroom pieces, but are not included in many of the more expensive modern suites. Owing to their partial decline in use oak. mahogany and painted wooden washstands can be picked up in reliable secondhand shops at comparatively low prices.

In some of the newer houses and flats hot and cold water fitted washatands are built into the bedrooms. Such washstands are cither concealed in a cupboard, or arc planned
over the part, or the old-fashioncd bluebag may be employed. Another homely but usually efficacious remedy is rubbing the stin? with a strong onion.

Destroying a Nest. Found in the ground or on grassy barks. wasps' nests can be destroyed in several ways, an old methorl being to burn them out with sulphur fumes. This method, however, is attended with some risk, especially to those inexperienced in the use of sulphur. A good plan is to pour some petrol in the opening late in the evening when the wasps are all in their nest, and seal up the hole with some clay. The next morning a little more petrol should be poured in, and then the nest can be dug out and destroyed. Cyanide of potassiuin can be used in the sanse way. The latter should be dissolved in water in the proportion of 3 dramıs to $\frac{1}{2}$ pint, and carcfully squirted into the opening of the wasps' nest with a small syringe.
Trap for Wasps. A wasp trap can very easily be made from a flower pot, a jam jar. and a saucer. The flower pot should be turned upside down, and raised from the ground on three sma!l blocks of wood. The jam jar is then placed over the hole in the bottom of the flower fot, and underneath the whole is the

Waste Paper Basket. Fig. 1. Gilded waste paper basket decorated with flowers in brightly coloured raffia. Fig. 2. Waste paper receptacle with; wood pulp foundation painted and decorated with old gower print
saucer with some sugar therein. The wasps silver or other coloured barbola work throwwill enter in the space between the bottom of ing the ground colour of the basket into the flower pot and the earth in order to eat the sugar. When satiated, they will fly up and through the bole in the flower pot into the inverted jam jar, where they will be caught.

To remove the wasps, a card should be placed between the mouth of the jar and the inverted bottom of the Hower pot. Keeping the card firmly fixed against the mouth oi the jar, this can be removed and immersed in water. drowning the wasps.

WASTE PAPER BASKET. Receptacles for holding waste paper and discarded scraps of other materials are necessary in all sitting. rooms and in most bedrooms. They can be bought very cheaply. especially the varieties in wicker, cane, rush, imitation leather and cardboard covered with cretonne. Metal baskets are constructed of interlaced steel boops and various forms of woven wire work.

Woven cane baskets are enhanced in appearance by barbola decoration (see Gesso Work), the contrasting tones of the gold, harmonious relief. The gilded cane waste
paper basket shown in Fig. l, embroidered in coloured raffia is a variation of the same type. The basket may be bought ready gilded or painted at home with metallic paint. The flowers should be loosely made (see Raffia Work), and two or three shades of pink may be used for each rose, the leaves and stems being worked with green raffia. The basket may be lined with silk and finished at the top with gold galon if desired.

Varieties of parchment covered waste paper receptacles can be obtained either plain or ready decorated. The one shown in Fig. 2 has a wood pulp foundation, is painted green, with a gilded rim and base, and lined with marbled paper. A beautiful old flower print has been used to ornament one side and the whole has then been varnished. Stencilled or hand painted designs would be an equally suitable form of decoration. See Writing Desk Set.

## Watches and Their Mechanism

## Simple Explanation of Different Types of Escapement

Aided by diagrams this article first describes the working of a watch, and in a subsequent section gives hints on the selection and care of this delicate apparatus. See also Clock
Watches small enough to be carried in the for watch cases and dials appeared. pocket were first invented in Nuremberg, the 18th and early 19th centuries pinchbeck about the year 1500 , by Peter Hele, a clock. maker, who devised the mainspring. In 1658 a step forward was made by the discovery of the balance spring, and in 1695 Tompion, the great London clockmaker, patented a cylinder escapement. In the early part of the 18th century Graham brought out his dead-beat escapement, while John Harrison invented the compensation balance to counteract irregularities of time-kseping owing to variations in the temperature. The keyless watch appeared during later Regency days, and after 1850 was made in great quantities in, and exported from, Switzerland.
Though watches have usually preserved a round and fairly flat shape, ball and square, oblong and lozenge forms have appeared from time to time. The watch belonging to Mary Queen of Scots, illustrated in this page, was made in the shape of a skull and beautifully wrought.
In the 17th century decoration in enamel
(q.v.) was used instead of gold for cases, and was sometimes as richly chased and engraved. Silver was extensively used and other examples had outer cases of shagreen, tortoiseshell, ctc. A fairly representative series in order of date is illustrated on page 1401.
The mechanism of the watch will be more readily understood if the article on Clock is first referred to. The num ber of wheels in a watch has always remained the same, variations in the number of teeth in wheels and pinions being made to suit the different escapements that have been used. The mainwheel gears into the centre pinion, which carries the hands. F'rom there the centre wheel gears into the third pinion and the third wheel into the

Watch. Memento Mori watch, be longing to Mary Queen of Scots and given by her to Mary Seaton
fourth pinion, to which is bitted the seconds hand The fourth wheel gears into the escapewheel pinion
Escapements. Various types of escapement have been devised, the first of these being the cylinder or horizontal. This comprises an escape wheel with wedge-shaped teeth, which stand up from the flat of the wheel on stalks. and work in and out of a steel cylinder, nearly half of which is cut away. On the cylinder is mounted the balance and spring, and in swinging it gets impulse from the inclined plane of the teeth rubbing against the edges of the cylinder. This escapement was never used extensively in England, as it was found that there was a tendency to excessive wear on the working parts. Swiss watchmakers got over the difficulty by making the cylinder and wheel of hardened steel, and this device is still in use in the cheaper grades of both Swiss and French watches.
Fig 1. shows a detached lever escapement. typical in the main of the form found in the great majority of modern watches. The balance has a free swing, the pallete $B$ and lever $C$ interposing between the wheel and the balance. Fitted on to the balance staff E is a stecl roller D withra jewelled impulse pin $F$ standing out at right angles to the face; the pallets and lever are fixed together and swing on an axis at $K$.
When the balance swings, carrying with it the roller, in the direction of the arrow, the impulse pin enters the notch of the lever, striking with sufficient energy to move the lever and pallets far enough to release the wheel looth from the locking face of the pallet. The wheel, actuated by the force of the mainspring, now moves forward in the direction indicated by the arrow, pushing the pallet out of its path. By the time that the wheel tooth has reached the end of the impulse face the other pallet will be in position to receive another tooth.
When the pallet was pushed aside it carried with it the lever in the same direction as the roller is travelling, and in its passage it imparts a blow to the impulse pin that sends the halance on with renewed energy. The impulse pin has a dual use, unlocking the pallets by giving a blow on one side of the notch of the lever and receiving a blow from the other. The balance in its swing coils up the balance spring until its energy is expended. Its motion is then reversed by the uncoiling of the spring, when it repeats its operation in the opposite direction.
In the roller a small crescent is cut out, and into this passes the guard pin H to prevent the escapement from unlocking except when the impulse pin is in the notch. There are two banking pins L , set one on each side of the lever to keep the motion of the lever within the desired limits. The locking faces of the pallets are cut back from the radial line, and this causes the teeth to draw the pallets inward towards the centre of the wheel, and the lever is bard up against the banking pins so that the guard pin is clear of the roller. The working faces of the pallets are jewelled, J , and are slightly rounded to lessen the friction.

There are some minor variants of this escapement. The Swiss, for example, have abandoned the pointed teeth and use a wheel with what are called club teeth M, Fig. 2 -that is, teeth with the tips formed into an inclined plane dividing the impulse face between the wheel teeth and pallets. Some escapements are made with a double roller, the guard pin working on a smaller roller

Watch. Typical specimens, 16th to 18 th centuries. Top row : 1 , Single band watch, brass, c. 1560 ; 2, Claud Viet, 1698 , shagreen case ; $3, W$. Tomlinson, $1699-1732$, silver; $4, \mathrm{H}$. Massey, 1692-1707, silver. Middle row: 5, T. Tompion, 1639-1713, gold; 6, H. Prevost, 1710, gold, with repoussé outer case: 7, J. Shearwood, 1769 , silver : 8, J. Harrison, 1683-1776, early work, case in Vernis Martin. Bottom row : 9, Robt. Fleetwood, 1760 , gold, in shagreen outer, case (back); 10, W. this the compensating balance is used, as in Fig. 4. The parts A and B are turned out of one piece of steel. on the outer edge of which is melted a brass band C twice as thick as then stcel band B. These two bands are cut through at opposite sides (D), close up to the arm. leaving the balance with two free ends.
With a rise in temperature an ordinary balance expands, and in so doing increases its diameter, which causes it to vibrate more slowly. With a drop in temperature the operation is reversed. The remedy for this is a com pensating balance. The compensated balance also expands with a rise in temperature but as brass expands more than steel the effect is that the brass bends the rim inward at the free ends. This causes the centre of gyration to approach the centre of motion in the opposite direction to which the mass would expand, thus restoring the balance to its former shape. Around the rim are a scrics of tapped holes, into which screws, E, are fitted, and these can be shifted from one hole to another to vary the compensation. There are also four timing screws F , which can be used for bringing the watch up to time by screwing in or out, thus decreasing or increasing the diameter of the balance.
The balance spring controls the number of vibrations a balance will malic in a given time, so that the strength of the spring is in proportion to the weight of the balance. The usual form of spring is the volute or flat spiral. The inner end is pinned to a collar which is fitted friction-tight on the balance staff, and the outer end is pinned to a stud in the balance cock or the plate. An overcoil or Bréguet spring has the outer coil bent upward and carried in a long curve over the flat plane of the spring towards the centre near which it is fixed. The advantage of this type of spring is that it distends in action on each side of the centre, thus relieving the balance pivots of a good deal of side friction.

The regulator of a watch is gencrally a steel underneat h the impulse roller $N$. The chronometer escapement is only used on very high. class watches, and clocks for use at sea.

Jewelling, two methods of which are shown in lig. 3, is a nother important part of a watch, clear of the jewel hole. Balance pivots arc index held down friction-tight by the end-piece always made this way. The jewels of a watch on the top of the balance cock. Its axis have no value as gems. Their only worth lies coincides with the centre of the balance, the in this useful function of making a smooth run- index finger pointing to a scale engraved $F$ and the pivots being run in bearings made from hard stones set into the brass plates and cocks. These tend to a smoother running and diminish wear. Some of the pivots run in holes alone, others havcendstones placed over the outside of the jewel hole, the pivots in this case taling a bearing on the ends, and the shoulder of the pivot, which is usually cone shaped, standing ning for the mechanism.
The Balance. With the ordinary plain steel, brass, or gold balance, changes in temperature cause variations in timekeeping through the metal expanding or contracting. To overcome

Fig 1

$S$ on the top of the balance cock. At the other end of the index there are two fine pins standing out at right angles. Between these pins passes the outer coil of the spring, about a quarter of a turn from the pinning-up stud, and from these pins to the centre is the effective length of the spring. As the regulator is moved the pins pass along the spring, shortening or lengthening its effective length and therefore making the balance vibrate faster or slower.
The Care of Watches. A watch should be purchased from a reputable watchmaker, who can give much useful information on the question of its choice. It is well to consider if the difference between a high grade watch and a cheaper one is of personal importance. The difference, apart from external details, such as the material of the case, etc., is one of service; a cheap article may serve for a time and give tolerably good results for the money paid. While it is uncommon to find a poor movement in an expensive case, it is by no means necessary to have a gold case in order to secure a good timepiece. Reliable movements in silver or other metal cases can be bought at quite moderate prices.

A watch is a delicate piece of apparatus which violence or ill usage will immediately put out of order, causing damage to its finely constructed parts and rendering necessary a visit to a repairer, with its attendant expense. In the average watch there are upwards of 150 parts, some microscopically minute, although for its size it is a robust as well as a most delicate machine. The watch should be wound at regular intervals, night or morning, and should be removed from the garment at night. To throw down a garment with the watch in the pocket is to risk damage to the delicate mechanism.
The mainspring of a watch is enclosed in a drum or barrel, and consists of a finely made steel ribbon. It is the motive force of the remaining wheels, comprising the whole train down to the balance wheel, which latter may make as many as 18,000 vibrations in an hour. Regular or irregular beats of the balance will indicate its condition : many watch troubles will arise from a defect hereabout, and on the accurate adjustment of the balance wheel and hair spring depends good timekeeping. The hair spring is so fine and sensitive that it should never be touched by any but an \&Overflow expert : it is most easily
damaged and put out of working order, and is usually costly to replace.
The question of periodical cleaning and readjustment is vital to good performance If a watch is allowed to run for years without this, attention the constant running friction will cause the lubricating oil to dry up, or on the other hand it may become thickened. If the oil dries up the effect on the fine pivots, running in dry bearings, can be imagined.
The regulating of a watch when gaining or losing is a delicate operation and is best performed by a watchmaker. The regulator is in close proximity to the balance wheel and hair spring, and if the alteration is made by an amateur a slip with any instrument that may be used may cause considerable damage to these parts. Further, the regulation is not always effectively made with the index or regulator, but may require to be done by way of alteration to the timing screws, to be seen around the balance whecl, and none but an expert should venture this. On some watches, again, the index is provided with a tiny micrometer screw adjustment.
 always connected up with a local supply, and this ensures to the housc an amount ample for clcansing purposes of all kinds, and of a quality good enough for drinking.

In country districts water for the former purpose is often obtained by the collecting of rain-rater, but this will not scrve for drinking. A supply of drinking water, therefore, is often secured by sinking a well but water from shallow wells in the neighbourhood of houses or of land grazed by livestock should be regarded with suspicion. A good plan is to pass all the drinking water through a filter, a process carried out in many homes. When this is done it is of vital importance that the filter be kept scrupulously clean; the filtering medium frequent!y renewed, or if of the poreclain candle type, washed and sterilized. If this is not carefully attended to, instead of filtering the germs from the water, it will add further germs. Water may be divided into hard and soft, cach with its own advantages and defects for washing and drinking purposes. It is quite possible to soften hard water,

The watch pocket should be kept free of dust, sea, the case front and back should be opened since a tiny particle of grit in the working parts will cause a stoppage, and necessitate a cleaning job for the watchmaker. If a watch stops for no apparent reason, it may nced re-winding. Apart from this, try gentle pressure on the winder, and if it fails to start, do not tamper with it, since a stoppage then indicates something amiss.
Should the user of a wrist watch inadvertently omit to remove it before entering a bath or the
sea, the case front and back should be opened
at the earliest moment, draining out all the water possible, after which the whole watch should be immersed in oil to prevent the steel parts becoming affected by rust. The watch should then be passed on to the watchmaker to deal with. If a watch keeps erratic time, it may be because it has become magnetized. The watchmaker will possess an instrument for testing and demagnetizing. which will correct this defect.

## Water Supply and Distribution

## Methods in Use in Town and Country

The subject of this article is touched upon in a large number of related entries in this work. A selection of these only is named here, but a perusal will suggest others: Cistern; Drains; Filter; Frost ; Hot Water Supply ; House ; Pipe ; Pump; Rainwater; Soakaway; Tap; Well

The water that forms the domestic water and this is sometimes done bv the company supply is obtained in a variety of ways. Houses that is in control of the supply. Water in towns and populous districts are almost softening apparatus for use in the home is dealt with later in this article.

The supply of water for domestic purposes may conveniently be divided into two branches, the external supply to the house and the internal arrangements for distributing. Rainfa!l constitutes the chief source of all supplies. For the water supply of towns, :ivers and lakes are dammed and reservoirs are filled from them. Distribution is effected by means of main pipcs. The water is purified by being made to pass through filter beds, which usually consist of concrete receptacles baving layers of different filtering material arranged in them. A typical filter bed has at the bottom a layer of large graded gravel, on the top of which is another layer of smaller grade gravel. This again has pea gravel on top of it, and above this a very thick layer of fine washed sand. Distribution from the purifiers to the houses is nsually accomplished by gravity, and in many cases the water has first to be pumped to a sufficiently high level to ensure adequate pressure.
With regard to the actual chemical contents of an ordinary public supply, the following analysis may be taken as typical in a rural district in England.

Grains Per
Gallon
Gallon
28.00

0.00042

Nitrogen as nitrites .. .. .. .. Absent.
Nitrogen as nitrates
0.017

Absent vegetable debris and mineral matter, and there was the faintest trace of iron.

In the case of country houses water supply may present a considerable problem, and the choice of a suitable system for its collection depends entirely on circumstances. Wells are still in use, and care is required to choose a site where the water is pure and free from decayed animal or vegetable matter.

The House Supply. The internal distribution of cold water throughout a house where a town main exists presents no difficulty, as the pressure is always ample to supply all foors. Where there is no main, however, a tank placed at the highest point available is essential, and the distribution to lower parts is accomplished by gravity. A common arrangement is to use a storage tank for the supply to the lavatory basins, bath and hot water system. the main being connected to the ground-floor laps only. Automatic regulation of the water to the tank or cistern is accom. plished by a ball valve.

Water from the main supply is carried from the main to the bousc by a service pipe generally of $\frac{3}{4} \mathrm{in}$. lead pipe, fitted with a stop cock situated below the pavement. The position of this stop cock should be noted and the cover should be examined from time to time to prevent
it becoming clogged up 'The service pipes is carried through the wall of the house at some convenient position, and is then connected up to the main internal distribution pipe. In the event of a burst pipe or during a severe frost the internal supply should be cut off at the stop cock by means of a T-handled key.
The usual arrangement of the supply main is indicated in Fig. I, which shows how the pipe is brought into a house provided with a cellar. In addition to a stop cock outside the house (usually in the forecourt), it is an advantage to fit an indoor stop cock at the point of entry into the house, as shown. In districts where the pressure is intermittent it is necessary to use a storage tank at the top of the building for use when the main supply is not operating. but in this case a tap should be fitted to the internal main supply pipe so that drinking water is oblainable direct Storage tanks are also necessary in all buildings possessing modern systems of domestic hot-water services.
The arrangement of the internal distribution of pipes for an intermittent supply is illus trated in Fig 1: the main supply is shown as a solid line and the supply from the tank as a double line It will the noted that the main supply pipe is fitted with an emptying cock; this should always be done and it should be at the lowest point of the pipe. In houses where the supply is obtained from a well or surface storage tank, the water should be carried direct to the upper tank, arrangements being made for emptying the tank at the lowest level of the internal piping. For bungalows in cases where the supply is obtained from rainwater from the roof. a convenient plan is to support a tank as high as possible close under the eaves. The support can be arranged as a cool storc or food
Storage tanks should be provided with u cover and must be periodically and frequently cleaned. Supply pipes should be accessible and not bedded in plaster, and internal pipes must be inclined towards the lowest point.
Water Softening Apparatus. The question of the hardness and softness of water for household purposes is important, and in some districts it is essential that artificial aid be used to render the water soft. The term hard is applied to water which has absorbed mineral compounds from the ground, generally some chemical compound of lime or magnesia

Water softening plants may be obtaincd in sizes suitable for any houschold, and a type of plant in general use for this purpose is the Permutit softener, illustrated in Fig. 2. The wrater is softened by a chemical compound through which it is made to pass. The cylinder shown in the photograph contains the compound, the upper tank containing a common salt solution which is regulated automatically and regenerates the permutit. If a quantity of dry salt is added at stated intervals the apparatus requires no further attention.
There arc a number of reliable apparatus on the market, functioning in somewhat the same manner. Sometimes there are considerations which prevent the installation of a plant for dealing with the entire water supply for the household, in which case it is possible to obtain small supplies of soft water for drinking, toilet, or culinary purposes by using

Most housewives know the deposit of "fur" or "scale" which forms on the kettle where water is hard, and can have some idea of the effects of this on the interiors of hot water pipes and boilers. Hard water has been replaced for various houschold purposes by rain water and distilled water in the past, but the first of these is uncertain in eupply and no always possible to obtain and the second is costly.
As soft water effects many economics in the household, the installation of a softening plant is worth consideration, espe cially as some reliable and effective water softeners are obtainable at very moderate prices. They require no ex penses of upkecp beyond the passing of a solution of ordinary salt in water through the appli ance at stated intervals, talic up little room and are noiseless.
The use of soft water in the kitchen produces immediate benefit and saving both of labour and moncy. Tea and coffee can be reduced in quan tity, as the full value is extracted by soft water. The latter is necessary when cooking vegetables to preserve colour
 and Havour 'I'he consumption or soaps for a portable apparatus connected a! will to a and Havour. The consumption of soaps fo kitchen, lavatory basin, or bath tap. Fig. 3 illustrates a typical softener of the smaller type. No plumbing is nccessary, the appliance being simply fastened to the wall, and the flexible connexion slipped over the nozzle of the tap.

Advantages of Soft Water. While some people claim that a certain degree of hardness makes drinking water more palatable, an excess renders it harmful. Organic purity of water may be attested, and yet inorganic purity may not be attained. The former refer to freedom from harmful bacteria, the latte: indicates the absence of chemical compounds which make watcr hard, as for example, salts of lime and magnesia. toilet and domestic use is reduced almost by unnecessary. For washing-up, the task is lessened when lime and magnesia have been removed and no chalky marks are !eft to polish off glass or silver ware The insoluble curd of soap which makes !aundry work difficult is obviated by soft water, in which a small quantity of flakes produce a copious lather.
WATER BED. In order to lessen friction and pressure and prevent bedsores in case where from paralysis or other illness patients must lie in bed for long periods at a stretch a water bed is often employed in place of a mattress. It is simply an india-rubber bag of the size of an ordinary mattress. A screw stopper is inserted in one corner of the mattress through which it is filled.
The patient should not be on the bed whilc it is filled and should be taken off before it is empticd. The water for filling should be at a temperature of $90^{\circ}$ and sufficient should be used to scparate properly the two surfaces when the patient is on it. On the other hand. it must not be too full or it will be uncomfortable. A water bed should be covered by a mackintosh shect, and a blanket beneath the shect. Sec Bed-making: Bed Sore.
WATER BISCUIT. These plain biscuits are made by rubbing 3 oz . butter into 1 lb flour, and adding sufficient water to mix the whole to a stiff dough. Knead the latter well, roll it out very thinly, and stamp it into biscuits. Prick cach biscuit on top and bake them until they are palc brown in colour

WATER BOTTLE. Glass bottles o holding water are ordinary household items but old ones, some of them unade before the incention or at least the general use of glass are regarded as curios and are prized accord ingly. Some of these are made of skin, but others are of metal, in some cases the precious metals being used for them, and examples may be seen in the various museums.

In the ordinary household the most usua type of water bottle employed is the one which is placed on the washstand. These are bought complete with one or two tumblers, and vary from plain to cut glass or crystal.
Flat-shaped water bottles of glass or aluminium, for carrying when out for a long walk, can be obtained in cases fitted with a long strap. See Hot Water Bottle.

WATERBRASH. The regurgitation of a watery acrid or acid material into the mouth from the stomach is a feature of some forms of indigestion, and is popularly known as waterhrash. It is usually accompanied by a hot sensation behind the breast-bone and in the throat, which is descibed as heartburn (q.v.) See Indigestion.
WATER CLOSET. Both the construc tion and the arrangement of water closets are governed by building acts and the regulations of the local sanitary authorities, and when any alteration or addition is contemplated such requirements must be observed.

The usual apparatus comprises a closet pan and a flushing device known as a waste-water preventer. This consists of a tank or cistern holding two or three gallons of water. When the water is released, it is forced down a vertical pipe and flushes out the pan. The amount of water in the cistern is regulated by a ball cock, which is generally made of thin copper and should be airtight, so that the bal Hoats on the surface of the water. Its function is automatically to raise a lever, which closes a valve and cuts off the supply of water to the cistern when it has reached a certain level.

Should this ball be punctured, it becomes partly filled with water and is no longel
sufficiently buoyant to close the valve with the result that the water continues to run into the cistern and escapes by the overflow pipe. The remedy is to turn off the water at the source of supply, or elsc temporarily to fasten up the valve and then remove the ball and lever. The water is expelled by enlarging the puncture and by warming the ball; then the surface is scraped clean and a small patch of thin copper soldered over the aperture.
If the ball is immersed in water, air bubbles will show at once if there is another leak, which can be remedied in a similar manner. If no air bubbles are visible, the ball may be considered watertight and can be replaced. Another cause of the cistern overflowing may be found in the lever gradually bending and not rising sufficiently. This is remedied by bending the lever to its proper shape with the aid of pliers and spanners. When the valve is the cause of the trouble, the remedy is to replace the worn washer with a new one.

The cleansing of a water closet should be carried out regularly, using a long-handled, stiff-bristled brush and one of the branded preparations or disinfectants which are put up for that purpose, failing which a few drops of hydrochloric acid may be dropped into the pan, which should be thoroughly flushed two or threc times in succession. See Ball Cock; Drains; Pipe; Sanitation.

WATER COLOUR. Damp is the worst enemy of water colour drawings, because its presence is often unsuspected before the damage has been donc. Common effects of damp are the crinkling up of the drawing and the appearance of mildew spots on its surface. Initial care in seeing that the drawing is properly set in its mount-the slightly sunk varicty is preferable-helps to prevent crinkling, but where doubt exists as to the dryness of a particular wall the frame should be kept clear with strips of cork glued at or near its points of contact with the wall. Cork studs about $\frac{1}{2} \mathrm{in}$. thick make a perfect nonconductor of damp. Mildew is very difficult to remove without injuring the drawing, but, if its presence is detected at an early stage, light rubbing with breadcrumbs may prevent its development. See Picture ; Print.
WATERCRESS. Watercress is a hardy perennial herb, and is a true nasturtium. It can be cultivated in gardens without a waterway so long as it is given a moist, shaded position. It will thrive in still water, but steps must be taken periodically to renew it, otherwise it may become foul.
Table Uses. Watercress is an adjunct to salad and is also uscful for sandwiches to be served for afternoon tea, or may be eaten with bread and butter at breakfast. It has medicinal qualities as a blood purificr. The cress must be very thoroughly cleansed and picked before being served at table, and the thick stalks removed. When added to

Water Lily. Soft pink flower of the variety Colossea. which blooms throughout the summer Courtesu ol Amateur Gardening
salads it is divided into sprays, but the leaves are always allowed to remain whole.

Many dishes are garnished with watercress, notably those which are egged and crumbed and fried. As a garnish for ducks, chickens, pigeons, or game it is, after washing and picking, heated over steam or in a cool oven and seasoned with pepper and salt.

WATER GARDEN. The simplest form of water garden is a small pool of which the sides and bottom have been made watertight with layers of cement. On clay land the pool may be rendered watertight by puddling, but it is safer to use cement.

Water lilies, set in shallow baskets filled with loamy soil and planted in April or May, are the best plants for a garden pool. There are many varieties suitable for deep or shallow water. Other attractive aquatic plants are the bog bean, Cape pondweed, and flowering rush (hottonia).

Those who possess some kind of waterway, be it shallow water, ditch, stream, or even bogland, can transform it into a charining adjunct of the garden proper. The mud of the water-edge will accommodate bold groups of Japanese irises in company with Spirea palmata. Then one may select the marsh marigold in single and double forms, together with the vivid orange globe flowers. Space may also be found for the swect flag, funkia, and Japanese primulas. The reed mace will find a home, but its growth must be kept under control. Where space is ample, gunneras, rodgersias and giant reeds are avail able for use. See Arrowhead.
WATERGLASS: For Eggs. As used for preserving eggs, this is a strong solution of silicate of sola and water, varying in specific gravity according to the amount of silicate that is dissolved. The strongest solution usually found has a specific gravity of $1 \cdot 7$, and contains about equal parts by weight of sodium silicate and water.

In preparing the waterglass for use, five or 10 times its bulk of clean boiling water should be added to the concentrated solution, the amount varying with its strength. The preparation should be quite cold before it is used. Experiments have shown that a 3 per cent solution, i.e. 3 parts by measure of the concentrated solution to 97 parts of water, yields as good results as the one of 10 per cent that is often recommended. A 5 per cent solution can be used with safety.

When the waterglass is added to the water, the two must be very carefully and thoroughly mixed. The eggs may be dipped in the waterglass and dried off, leaving a film on the shells and then stored upon shelves, or they may be kept in the liquid until wanted. The latter method is preferable. When.taken out of the solution they should be washed. See Egg.

WATER JUG. Water jugs were made in the 18th century, and some of these are beautiful specimens of cut glass. Others were of pottcry or china, made in plain, fancy and sometimes grotesque shapes. Most of those in use to-day are based on 18th century patterns, or else are of coloured glass, modern in form, and sold to match sets of tumblers. See Glass Ware.
WATER LILY. The nymphaea or water lily makes a charming display in the summer months in a garden pool or even in tubs sunk in the ground. It must be planted in still water open to the sunshine : running water is too cold and it does not flourish in the shade. The larger kinds need 2 to 3 ft . depth of water but the smaller kinds flourish in a pool 18 in . decp, and the miniature water lilies are happy in 12 in . depth of water. The way to plant them is to place the roots in a basket filled with loamy (turfy) soil and manure, weight them with stones, and sink them to the bottom of the pool in April or May. The
baskets will gradually decap. The smallest of all water lilies suitable for tubs or for a shallow pool are pygmaea, white; pygmaea helvola, yellow ; odorata alba, white ; and Luciana, rose.
One of the loveliest of the water lilies suitable for cultivation in a tank or large tub in a heated glasshouse is the blue Nymphaea stellata. If this water lily is started into growth under glass in a tub of water it may be placed out of doors for the summer months. See Lily; Victoria Water Lily.

WATER MELON. The water melon. which is one of the two chicf varieties of melon, the other being known as the musk melon, is a popular dessert fruit and is also sometimes served as hors d'ocuvres. Several different kinds are grown, three of the best bcing known as the Spanish, apple-sceded, and the citron water melon. See Cantaloup; Melon.

## Water on the Brain. See Hydrocephalus.

WATERPROOF. The name waterproof is given to mackintoshes and any other coats which have been so treated in manufacture as to be impervious to wet. Oilskins and cloth raincoats are in this category, and coats made of material that will not in itself withstand the rain are often lined with rubber. All such garments sloould have ventilation boles.
WATERPROOFING. Rubber is the most reliable substance for rendering fabrics impervious to water. There are other commercial processes which are used in the manufacture of rainproof cloths, and they depend mainly on the reaction between two or more substances which causes a substance insoluble in water to be deposited in the fibres of the material.

The process of treating calico and other thin materials with both raw and boiled linseed oil forms another method of waterproofing. It can be carried out by the amateur. The oil should be brushed very sparing!y and dried in a current of air. If the material can be placed out of doors in a position free from dust, it will dry quicker, but the best method is to place it in a room near an open window, which should be covered with fine muslin. Three or four thin coats of oil will be necessary ; raw linseed oil makes the material more flexible, but it takes much longer to dry. A little gold size is sometimes added to the oil, in the proportions of 1 oz . to 16 oz . of oil, to assist the drying. If it is desired to make the material black, the method is to thin some black paint with turps and apply it when the last coat of oil is dry.

Coarse canvas for use as awnings, covers, and tents can be waterproofed by applying a solution made by mixing 1 part of sulphate of zinc and $1 \frac{1}{2}$ parts of sulphate of iron with 18 parts of linseed oil and boiling it for two hours. When cool, add 15 parts of oil of turpentine and any colouring matter desired. The canvas should be left to dry for a week and a sccond application will complete the process.

Methods of rendering brick work and concrete resistant to damp and the action of driving rain or falling water are described in the article on Damp.

WATER RATE. This describes the charge made for the use of water by the municipalities and public companies that provide it. It is payable by all householders to whose premises the water is laid on, and is calculated at 5 or some other percentage on the rateable valuc the amount being fixed by Act of Parliament. It is usually payable every quarter, but in London every half year, and landlords who themsclves pay the rates on the houses they let pay also the water rate.

Water companies make an extra charge to persons who require water for other than strictly household purposes, e.g. those who have a garden hose or a garage or stables. If the water rate is not paid when it becomes due, the supply may be cut off and the occupier of the premises summoned. See Rates.

WATT, In electricity a watt is the unit of electrical power. It is the power exerted by a current of one ampere flowing under a pressure of one volt. A horsc power is 746 watts. See Electric Light.

WATTEAU STYLE. Paintings or decorative designs imitated from the work of Antoinc Wattearr; a French artist of the early 18th century, are said to be in the Watteau stylc.

Graceful fantasies of figures, in the court or pierrot costume of the period, set in a landscape of park or garden, the subjects are sentimental comedy or romance, the colouring is delicate, and the figures dainty, but at the same time realistic and beautifully drawn. Statuce of nymphs, musical instruments, and garlands appear in many of the compositions.
The style is used in mural and cciling decorations for rooms to be furnished in imitation of this period. The ornamentation is often arranged in medallions connected by garlands. Designs for rapestry to upholster the gilt furniture of his time, for paintings on screens, on cabinet pancls, on china and on fans are also often in so-called Watteau style.

Watteau style in dress usually refers to the sacque or overdress in which he painted so many of his court ladies, and particularly to the pleated fold at the back of the neck which flutes out into the skirt and is known as the Watteau pleat. See Fan.

WATTLE. This word is employed in two main senses. It refers to various Australian species of the acacia. This wattle has become closely associnted with that country, and one of the principal Australian holidays is called Wattle Day. The name is sometimes given to the twigs or rods of the willow. See Mimosa.
WAVE-LENGTH: In Wireless. This is the distance betwcen the crests of two successive elcetro-magnctic waves and is equal to $-\frac{V}{\mathrm{~F}}$, where $\mathrm{V}=$ the velocity of the wave in metres per second, and $F=$ the frequency in cycles per second. The velocity of an electromagnetic wave is 300 million metres (approx. 186,000 miles) per second.
WAVE-METER. This is an apparatus for measuring wave-length. There arc three main types, viz. buzzer, heterodyne, and absorption. Buzzer wave-meters comprise a tuned circuit having an inductance coil and shunted by a variable condenser, a high-note buzzer being used to produce oscillatory currents in the circuit.
The wave-meter is placed near the circuit whose wave-length is to be measured and the wave-meter condenser is adjusted until the buzzer note is heard in the loud speaker or telephones attached to the receiver. The buzzer note will be heard most loudly when the meter is in tune with the circuit undergoing measurement, and the wave-length can then be read off on the meter calibration chart.
A heterodyne wave-meter employs an oscillating valve and is capable of giving very accurate measurements. To measure the wavelength of a station, the tuning control on the receiver is sct to the required transmission and the meter condenser is rotated until a squeal is heard in the loud speaker or telephones. This denotes that the wave-meter is heterodyning the carrier wave of the broadcasting station.
If the meter condenser is adjusted further the squeal will hecome lower in pitch, pass through a " silent point" and then gradually rise in pitch. The silent point is the correct adjustment and indicates that the wavc-meter and carrier-wave are exactly in step. The wavelength can then be read off on the chart.

For short-wave rcception, absorption meters are sometimes employed. These consist simply of an inductance coil and condenser. The wave-meter inductance is placed closo to the
tuning inductance of the short-wave set. If the set is tuned to a distant telephony transmission there will be a marked diminution in the volume of the station being received when the meter condenser is adjusted to that station's wave-length. See Heterndyne.

Wax Dyeing. See Batik.
WAX FLOWER. This is the popular name of an evergreen plant of slender climbing growth, with wax-like flowers, suitable only for cultivation under glass. The commonest kind is Hoya carnosa, which needs a minimum temperature of about 55 degrees and bears white flowers tinged with pink. It should be planted in a tub, well drained, and filled with a compost of loam, peat and sand. Propagation is by cuttings inserted in sandy soil heneath a propagating case in spring.

WEANING. An infant at the breast should be weaned gradually when it is nine months old. A meal of cornHour, arrowroot, barley jelly or something similar, with cow's milk, is substituted for a brcast feed, and in the course of a few weeks the child should have a! its meals of the latter description. Should the time for weaning fall in hot weather, or when the child's health is disturbed by teething or some other causc, weaning should be post-
poned till the circumstances are more favour. able. See Baby.

WEATHERBOARD. The particular class of timber knowil as weatherboard is used extensively in the construction of amall buildings. It is commonly made with a feather edge and is wedge-shaped in section, being lin. thick on one side and $\frac{1}{4} \mathrm{in}$. on the other, averaging in width 5 to 6 in.
The boards are weather-tight in virtue of their cbaracteristic overlap, the lower colge of one plank orerlapping by about an inch the upper edge of the plank bencath it.

It would be undesirable to expose the end grain of the weatherboard to the full force of the weather: and for this reason vertical timbers, or cover strips, shonld be employed at all external angles. These strips are erected first, and the weatherhoard fitted into the space between them when the timber is of sufficient length to reach from one side of the wall to the other side.

In addition to the ordinary form it is possible to get rebated weatherboard, the use of which permits of a Hat surface on the inside. Vor good rork T. and G. matched weatherboard should be used. See Board : Draught ; House.

## Weaving in the Home

## With Descriptions of Various Kinds of Loom

This article deals with a domestic industry that is becoming increasingly popular. Aiter a clear description of a typical loom and its mechanism the reader is told how to weave a pece of matcrial suitable for covering chairs, settec, ctc. The article loom maly also be profitably consulted

It is not necessary to provide a large loom Greater speed is possible, and more intricate in order to gain some practical experience of weaving in its simplest form ; narrow materials, braids, trimming, and ties can be made on a board loom of quite simple construction, as illustrated in page 743 of this Encyclopedia. The material produced is weaving in its simplest form, depending on colour for its cffect; but it thoroughly illustrates the essentials of the craft. The proportions of this simple appliance can be increased, but for anything but the simplest work the table loom shown in the same page is recommencled. It is not expensive to purchase, and can be obtained in widths from 18 in . to 33 in ., made cither as a simple loom, as ilhstrated, or with four hoddles, manipulated by cords.

In a pedal loom the heddles arc operated by the feet, and four or more can readily be manipulated, the hands being left free for passing the shuttle and beating the weft.

Weaving. Fig. 1. Hand loom. A, warp stretching from roller to roller. B, lease rods. C, porrey cross. D, heddles. E, reed. F, sleigh. G, breast roller. H, treadles. K. grooves in roller. L, pawl and ratchet
wheel. M, aroove in roller. N. friction brake. O, weight beam. P, beam ward or cane roller. Q. weaver's seat

Weaving. Figs. 2 (abcvc) and 3. Showing a simple warping board, together with the necessary constructional Fimension further details see text

Having selected the warp yarn, decide on the length of material to be made. In calculating the length, at least 18 in or 2 ft . extra of warp thread must be allowed, as it is impossible to weave right up to the end of the threads. The desired width of the material must also be settled, and number of warp threads to the inch ascertained A very good warp for a beginner is thick cotton. This can be used at twenty ends or threads to the inch, and is recommended because its strength and durability render it less liable to break.
Laying a Plain Warp. The chiet thing to bear in mind in making a warp is that all the warp threads must be of equal length. A simple method of getting a series ol cords the same length is by fixing in a board hung on the wal: a number of wooden pega, arranged more or les: after the manner in Fig 2 A dimensioned drawing of the warping board is given in Fig. B3. The pegs (A. B), shown in solid blact, are loose and may be withdrawn from the board, the other pegs being firmly fixed. With the warp thread reeled or spooled, and resting on a thick wire supported on a frame (Fig i). so that the reel or spool will rotate, hegin by looping the end of the warp to the peg of the warping hoard marked $A$

Proceed in the direction marked by the arrow to the left under the first peg. over the second, over the corner pegs 3, 4 and 5 ; then round 6 and back to 7 ; thence to 8 and round 9 under 10 . Next the thread goes over and round $B$, over 10 . thence to 9 and so back to peg 3, passing over 8, 7,6, is and 4 in turn From 3 the thrend is continucd under 2 . over 1 , and under $A$ This must be repeated until the number of threads on the pege $A$ and 13 corresponds $w$-ith those required for the width of the niaterial. Favh forward and each backward run of the thead equals one warp thread a complete course from $A$ to $B$ and back again to A equalling two warp threads Both ends of the warp A to B must now be secured with cords, tightly fastened. Similar cords must be tied at the porrey cross, betwcen 2 and 1 , and the portéc cross, between $B$ and 10, but in these two instances the cords must be long, tied tight!y at the ends, and looped near to the cross These instructions apply to a plain warp. Instructions for laying a striped warp are given in a later section dealing with the weaving of an upholstery inaterial.
The required number of threads having been made, take off warp at peg $B$ and loop warp as if making a crochet chain (Fig. 9) until peg A is reached Insert a smooth stick or iron rod $\frac{3}{8} \mathrm{in}$. or $\frac{1}{2} \mathrm{in}$. diameter through loop.
Beaming the Warp. The raddle is illustrated in Fig. 4, and is a simple framework of wood. The cap, or upper part of the frame, lifte off, displaying a scries of strong wires fixed into the lower part of frame, in this case spaced five to the inch It is between these wires or dents that the warp threads are now to be distributed The suggested warp had twenty threads to the inch, so in order to spread the threads evenly across the loom it will be neces.
sary to put four warp ends together in a space or dent of the raddle On some looms (c.g. the one shown in Fig. 4, page 744) the raddle can be inscrted temporarily in the frame of the batten in place of the reed

Having spread the warp, return the cap to its place, sceing that all the wires are settied in the groove of the cap. Then make it secure by tying cords at either end of the raddle, so that there is no possibility of the cap becoming delached. All is now ready for the warp to be wound or turned or beamed to the warp ro!!er at the back of the loom, as shown

Weaving. Fig. 1. Raddle and stand with warn ready for distributing in dents of raddle. Below raddle shown with cep lifted
in Fig. l, and it is important to spread the warp as eveniy as possible on the warp or cane roller. This can be done by first lifting the iron rod over which the warp is spread and placing it in the groove of the back roller, where it is secured with cords The triangle (Fig. 5) is heavily weighted and placed as far away as possible from the loom, keeping the point to the middle of the loom. Next proceed carcfully to turn the warp on to the roller This is accomplished by means of the turning stick, which is passed through a hole in the end of the roller. Turn the roller until all but a foot or two are on. or uatil the cross in the warp nearest $A$ on the warping board has been ncarly reached. Two round, smooth sticks bout $\frac{1}{d}$ in or $\frac{3}{8}$ in in diameter will now be wanted These are the lease rods, and take the place of the loop ol cord between 1 and 2 in the warp called the porrey cross They will require some support and can be looped up with two cords attached to back and front rollers of loom, as at Fig. 1, B To prevent conusion, tie the warps in group: with a loop.

Making the Heddles. The heddles, which carry the warp, are composed of groups of leashessct on shafts or frames of wood. Each eye in the leash has a warp thread passord

Fig 5. The triangle together with disaram showing measurementa and method oí constriction
through it, and the action of treadling causes the warp threads to rise or fall, making a space between the warps which is technically known as the rising or lowering shed. These leashes can be purchased or may be made on a small board formed as shown in Fig. 8 It is made of a piece of $\frac{3}{4} \mathrm{in}$ board having four pieces of dowe! stick fixed firmly in it. as shown in the illustration

Cut a number of cords of the correct lengtb. Mcasure one by hooking around first peg and taking the double coid down to the pointed end of heddle board where it can be cut. This gives the length of cord required Test one leash to make sure.

In order to make the process clear we may call the pegs $A, B, C$ and $D$, commencing with the left-hand one Begin with a picce of cord by looping it round $\mathbf{A}$ and tying off firmly at $B$, leaving both ends the same length. Then, without cutting, loop round C and tic again finally tie around D and leave the ends uncut. Simple reef knote should be made, and below $B$ and $C$ the cord can be twisted. Fig 4 shows very clearly how the loops are made The loop around C is the "eye " of the leash

Having made sufficient leashes, one for each warp thread, hang them on two thin laths of wood suspenderl by cords, and the licddle is ready to hang in its place in the loom. as at Fig. 1. D. Two sets of these will be required. that is to say, if 100 ends of warphavebecn warped up, it will be necessary to have 50 leashes on cach heddle. The heddle laths should be so arranged in the loom that the cye in the leash is on a level with the tops of the rollers.
The next process consists in picking up the warp threads and entering each, that is, passing the end through an cye of the leash. The warp must take a straight course, and not get twisted round the cye or through the lower or upper loop of the leash. First a back leash is entered, then a front, and so on alternately across the loom, the work being done from left to right.

The batten or sleigh, Fig. 1, F, contains the comb or reed, E . This is made with steel wire, which furnishes spaces of various sizes according to the requirements of the particular work in hand. Some have ten spaces or dents to the inch, some twelve or twenty. For ordinary work a ten or twenty reed will be found very useful We will assume that a t wenty gauge reed is heing employed in the work now leeing described. In arranging the work, as staled above, twenty warp ends were allowed to every inch, so that one warp thread will be entered or passed through each dent or space in the reed ; in the case of ten warp ends to the inch, every other dent would have been left empty; or in the case of forty warp ends to the inch, two threads would be entered together in each dent or space. Al. though a reed can be made with almost any number of dents, coarse or fine work can be done in a twenty rced. For very coarse work, such as thick canvas or rugs, ten or even five dents to the inch would be considerably more suitable.
To prevent confusion at
this slage in gaiting or entering the loom, loop the warps
into groups. Take two iron rods, $\frac{1}{2} \mathrm{in}$. in diameter, and two long pieces of strong cord. Loop the double ends of each cord round the ends of the first rod, and drop it into the groove in the cloth or front roller, Fig. 1, G, and Fig. 6, 0 ; secure firmly with cords, and wind the ends of the cords round the roller until only 6 or 7 in . of the cord hang over. These ends are now to be secured to the ends of the second iron rod, which has been fastened in the same manner to beam warp or cane roller $P$, Fig. 1, and with two small weights attached to the ends, is supported by the reed immediately in front. For the purpose of tying the ends of the warps firmly to the second iron rod several methods can be employed. Take a group of warp threads and pass them over the second iron rod; turn them under, and in the process divide them so that as they come up on the other side of the iron rod half will be on the right of the original group of threads, and half on the left. Tie
first a knot, then a double bow.
The point to aim at is that the warp threads pattern on squared paper; also the tie-up of shall be securely held at about the same the threads, entering through heddles and reed, tension right across the loom. This completes what is called the tie-up of the warp threads.

It now remains to tie up the heddles and treadles, Fig. 6. In order to prevent the sagging of the warp, a friction brake is applied to the beam warp. This consists of a rope wound once or twice round it and tightened with weights, as shown at O, Fig. 1.

The shuttle, Fig. 10, is the wooden instrument or tool which carries the quill containing the weft to and fro across
the loom. The correct way
ent rue correct way and a piece of the fabric woven. Many variations of form and colour are possible with this simple setting up of the loom. There is no limit to the variety of patterns known as weft stripes, formed by a certain number of passes to represent the width of the band.

Weaving a Chair Cover. Fig. 11 illustrates a portion of a piece of material woven on a table loom, for the purpose of covering chairs or a settee. Its application is wider, however, for it can be used for window curtains and other hangings. The warp is of linen in various colours so arranged as to produce a striped effect. The weft is of blue spun silk, a material which, on account of its relatively lighter weight, is less expensive to use than artificial silks. The piece is 12 yd . long and 33 in . wide. The following instructions apply specifically to a table loom of the type illustrated on page 743 of this work.
of threading the shuttle is shown in the illustration.

First Steps in Weaving. One method of making a pass is to depress the right treadle H , pressing the batten back with the left hand, while the right hand has the shuttle ready to throw across the loom through the shed caused by the lowering of the warp threads in the first heddle $D$. The shuttle having passed from the right hand to the left, the right is now free to press back the batten or sleigh. The left foot must now depress the other treadle, when all the warp threads attached to the second heddle will be lowered, leaving an opening or shed in the warp through which the shuttle is thrown to the right hand.

Beat up the weft with the batten by pulling it forward, and by repeating this sequence of operations the fabric will begin to appear, the kind of weaving produced being what is known as plain weaving or tabby.

A glance at Fig. 6 will show a plan and sectional elevation of the warp and draft or

Fig. 7. Spool rack. Fig. 8. Heddie board showing dimensions. Fig. 8. Warp chain showing ties made at crossings. Fig. 10. Simple form of shuttle showing how thread comes off spool on top and is led through eye brown are reached. of peg A, 1, 2 and B, making 8 ties in all.

The Warp. In the warp there are 24 strands strands are under one crossing stick and two to the inch, and since the width is 33 in ., the over, alternately all the way.
latter number multiplied by $24(=792)$, gives us the total number of warp threads needed. In laying the warp a spool-holder (Fig. 7) is used to hold bobbins or spools. Place 2 spools of brown cotton on spool-holder, knot ends of threads together, and place on peg $A$ of warping board. Continue round peg 1 to 2 (forming crossing), thence to numbers 3,4 , $5,6,7,8$ and 9 , finishing at 10 and $B$, taking threads round peg $B$ and back the same way to peg 2, crossing threads reverse way to 1 round peg A. (See Figs. 2 and 3 on p. 1406.

Continue laying the threads as follows: 22 brown, making in all *24, 8 fawn, 4 brown, 2 orange, 2 yellow, 4 green, 2 mauve, 2 blue, 2 mauve, 2 blue, 4 green, 2 orange, 12 fawn, 2 orange, 4 greon, 2 blue, 2 mauve, 2 blue, 2 mauve, 4 green, 2 yellow, 2 orange, 4 brown 8 fawn, 2 brown, 2 fawn, 2 brown, 2 fawn, 2 orange. [1 brown, 1 fawn; repeat four times.] 2 orange, 2 blue, 2 yellow, 2 fawn, 2 brown, 2 fawn, 2 brown **; *** [ 42 fawn, 2 brown, 2 fawn, 2 brown, 2 fawn, 1 brown, 1 fawn, 8 times; 2 fawn, 2 brown, 4 times; 42 threads fawn.] Repeat from *** ( 42 fawn, etc.) four times in all. This forms one complete unit of design. Next repeat pattern backwards start ing from ** ( 2 brown, 2 fawn, etc.) until 24

This finishes the laying of the warp. When only two threads are needed it is best to leave at peg $B$ until required again, or if at peg $B$, leave at peg A. Do not take the same 2 threads back, as otherwise there would be 4 threads instead of 2. Knot threads same way to finish as detailed for the beginning. Tie each side

Take off warp at peg B, and loop warp as if making a crochet chain until peg $A$ is reached (see Fig. 9). Insert a smooth stick through loop and tie this on to front beam of table loom. Place crossing sticks through tie ups of pegs 1 and 2, making sure warp is not twisted. Tie string across sticks to keep in place. Then cut through top ties made at $\operatorname{peg} A$, and take out the crossing. It will be seen that two

Threading the Warp. Tie a twelve gauge reed in position so that it will not move while threading, then turn handle at side, so that one line of heddles is up and one down; make sure that eye is seen from back of loom. Pass reed hook through first eyelet and then through first dent of reed; take first pair of threads from crossing and, hooking one on reed hook, draw through to back of loom. Place hook in lower eyelet and through same dent, drawing thread through in a similar way. Continue thus until all the threads are entered, two in each dent,
up to the entire width of the warp It is best to thread an inch at a time and tie up separately, also to have instruction paper in front of the worker so as to check stripes in warp.

Fasten loom firmly on to a table, so that it can resist the pull of the warp in beaming on. Place triangle, heavily weighted, on the floor as far away as possible, keeping point of triangle to the middle of loom. It is very important to see that eyelets are closed in one line before warping up. Do not take out crossing sticks. Undo chain as far as triangle. Next take first bunch of threads and pull up tight (leaving no loose ones), and tie on stick at back roller, half und and on a between

Weaving. Fig. 11. Hand woven material for chair cover (part width only shown). Border is repeated at right margin, with
brown atripes on a fawn ground between
the batten to press up firmly when beating the weft between each pass. It is necessary to keep the edges of the warp thread and woven material even when winding up, and also to maintain an equal tension all through the piece. After winding on the woven material as described, lift the batten nearer to the front in the first notch and continue weaving again. This sequence of operations is carried out at intervals until the entire warp is finished:

The quantities of linen needed for the warp in the various colours are as follows: Brown, 8 oz. : fawn, 2 lb .8 oz ; orange, $4 \mathrm{oz}$. ; yellow, 2 oz. : green, 2 oz. ; mauve, Blue spun silk is suggested over The stick passes through a number for the weft and $1 \frac{1}{2}$ oz. per yard will be of loops at back of loom. It is best to tie needed. The colour could be varicd to give one inch at each end and one in the middle, and continue until all bunches are tied, at an even tension.
Take crossing sticks down through the warp to triangle, making sure that there are no loose threads or ends. The end of the warp chain is looped over the post of triangle and secured by the peg. This leeps the unbeamed portion of the warp taut and even while winding on is in progress. Place a sheet of paper over the layer of threads on back roller and turn roller, so winding on the warp, until triangle is pulled up to loom. Now take triangle down again (away from loom) and proceed in a similar manner until warp is finished It must be noted that each time the triangle is pulled up close to the loom by the winding on and consequent shortening of the chain of warp, a number of loops of warp chain are to be freed, and the chain secured again. When warp is finished, cut through ties B, take out crossing sticks, open harness and tie on to front stick in the same manner as at the back of loom, but putting the "unders "under the stick, and tie to tops. Continue until finished, when the loom is ready for weaving.
The Weaving. Blue spun silk is used for the weft, but a linen could be utilized, and would make a stronger fabric. Place a spool in shuttle, clamp loom on a table about 25 in. high so that a comfortable sitting position is obtained (see illustration in page 743). Turn the handle at side of loom, which will operate the heddle roller and cause one set of heddles to fall and one to rise, thus forming a " shed " or opening of the threads. Throw the shuttle through "shed " from right to left, catch the shuttle on the left side, bring batten forward as far as it will come. Hold the batten in the centre with the left hand, at the same time turning the handle in the opposite direction to that first used. Push battegn back, throw shuttle through shed from left to right, eatch the shuttle with the right hand, and pull the batten forward to beat as before. Now change the shed by turning the handle opposite way.

Continue weaving until there is insufficient opening to pass shuttle through, when the batten can be set further back by lifting up and moving over one or two notches, so that a good opening is obtained again. Continue weaving further until shed becomes too small for shuttle, when some of the woven material must be wound on to roller. Release the back roller, wind the material round the front roller, placing a sheet of paper between layers to keep the material clean and even. It is important to leave sufficient of the material unwound for
needed. The colour could be varicd to give a banded effect, if desired. Linen might be
used for the weft, instead of silk, if a stronger and more durable fabric is required. The piece of cloth from which our illustration was made was woven for the purpose by the Alston Weaving Studios, from whom

Wedding invitations should be issued from three weeks to a fortnight before the wedding day. They are sent out in the names of the bride's parents or near relative, by either of whom a luncheon or reception is usually given after the ceremony. In the case of a young widow living with her parents, the invitations would be sent out in their names, but if she is living in her own home, in her own.

People invited to a wedding send wedding presents either to the bride or bridegroom. Sometimes this is done as soon as the engagement is announced, and in that case an invitation should be sent to anyone who has given a present, even if there is little chance that he or she will be able to attend the ceremony. Presents are always displayed at the reception, and a special afternoon tea is sometimes given, also for this purpose, previous to the wedding day. They should be attractively arranged, and a card bearing the name of the giver placed on or close to each present.
Wedding Expenses. The chief expenses of a wedding fall on the bride's parents, or relative who stands in their place. The cost of the trousseau, dinners, and at homes given to introduce the bridegroom to the bride's family, the reception, whether given at the house or at an hotel, are all defrayed by them. A choral service, the fees of the organist, choirmaster, and choir, also the printing of leaflets for the special hymns to be sung on the occasion, and the newspaper announcements of the wedding, all floral decorations, the hire of the awning and felt at the church doors, and wedding buttonholes are paid for by them. The bridegroom provides the ring, and bouquets for bride and bridesmaids, and it is usual for him to make a present to each of the bridesmaids. He also provides the car to take himself and the bride from the church to the reception and away to the honeymoon destination or railway station for this afterwards. Should the bride's father have a car of his own,
suitable yarns may be obtained. The material would also make curtains, table runners, and cushions. By using three complete widths it might be employed for a bedspread; the widths could be joined either by a handwoven braid or trimming of narrow width, by a knitted insertion (see page 628) in silk to tone, or by faggoting (q.v.). Handwoven materials for upholstery and furnishing require little trimming as their decorative value lies in colour and texture. Heavy tassels, plain cords, narrow silk fringes, gimps and tinsel galons are suitable finishes for cushions. curtains and runners.

WEBBING: In Upholstery. In uphol stery, webbing in the form of a wide tape is used for supporting the stuffing and springs of chairs. There are two kinds, the best being English, which is recognized by its black and white diagonal pattern. Its strength is known by numbers, Nos. 10,12 , and 14 being in general use. English web is put up in pieces of 18 yd . A cheaper quality is woven in stripes, and the sizes are known by the number of stripes of colour in the width. It is usually put up in pieces of 36 yd .
Although webbing is a closely woven material, it stretches in use, and when it is attached to a chair frame it is necessary to stretch it as much as possible. The upholsterer uses special pliers for this purpose (illustrated in use on page 1353), but it is generally possible to use a short length of generaly possib
wood as a lever.

## Wedding Arrangements and Etiquette

## How to Plan the Reception and the Refreshments

## This contribution dea's 'with the ceremonial and social observances for the occasion. References should be made to the article on Marriage. See also the entries on At Home; Banns; Best Man; Bouquet; Bride; Bridegroom; Bridesmaid; Cake; Ice; Luncheon; Sandwich; Supper

it is sometimes lent for the latter purpose. The bridegroom also pays the fees connected with the ceremony. It is also customary for him to provide the furniture and accessories for the new home, though these are often supplemented by the wedding presents.

The Ceremony. Afternoon weddings are usually at 2.30 o'clock. Quieter weddings take place in the mornings, the hours when marriages can be solemnised being from 8 a.m. to 3 p.m. The best man, usually a bachelor, should either accompany the bridegroom to the church or meet him there. They both await the bride at the right-hand side of the chancel gates. The best man stands on the right of the bridegroom during the wedding ceremony; he should sign the register in the vestry afterwards and pay the fees if the bridegroom does not do so on arrival.

The bride is driven to church with either her father or mother. Should the father be dead, the bride is given away by a near male relative, who meets her at the church door. Should there be sisters who are acting as bridesmaids, the mother often precedes the bride to church and with the bridesmaids awaits her inside the doors. When the bride and her father arrive she takes his right arm while walking up to the chancel. At choral weddings the clergy and choir head the bridal procession to the chancel, singing a hymn. The bridesmaids follow the bride, and her mother walks next with a near male relative.

The relatives in either family seat themselves in pews, the bridegroom's relatives on the right-hand side of the nave, the bride's on the left. The bride stands at the bridegroom's left hand, with the person who is to give her away on her left. The bridesmaids stand immediately behind the bride, and the chief bridesmaid holds her gloves, if she has these, and bouquet from the commencement of the service. After the service is over the bride takes the bridegroom's left arm, and, preceded
by the officiating clergyman, and followed b the chief bridesmaid, best man, father, mother, and most distinguished guests present, they enter the vestry to sign the register. After this the bride takes the bridegroom's left arm and passes down the aisle, followed by the bridesmaids. The married couple should leave the church without shaking hands, etc., with friends, if a reception is to follow The bride's mother should he the next to leave the church, in order that she may reach home to receive her guests.
In the case of $n$ widow, it is optional whether she is given away or not. She does not have bridesmains, but may have pages, should the wedding be a fashionable one. She may have a wodding calie, but it should not be decorated with orange blossoms.
Wedding Reception. Wedding luncheons are usually given at receptions only when the party is comparatively a small one, and the wedding has been held in the morning, or at country weddings. The menu is that of a seasonable luncheon. It is usual to begin the actual meal about half an hour after the guests have assembled at the bride's house or whereever the reception is being held Cocktails and appetizers are offered first and afterwards the luncheon is served. Wedding cake and champagne are included on the menu.

Plate for service, a wedding cake linife, and decorative accessories such as a houquet holder, flower vases, and a wedding cake stand can be hired inexpensively from a firm of caterers. Floral decorations are of first importance, and should tone with the colour scheme of the bridesmaids' dresses, or may be of all white flowers. China, glass, and silver ware and also the embroidered or lace rumer or lace trimmed cloth on the buffet or dining table should all be chosen with regard to the occasion. If white flowers are used, amber or green glasses will look well. A background of palnis, ferns, flowering plants and arrangements of cut flowers to tone with the other floral decorations is usually made in one part of the reception-room where the bridal pair will stand to receive congratulations before luncheon is served in the dining room, or the cake is cut and light refreshments provided.

When only a reception is given at an afternoon wedding, such refreshments are much the same as those at an At Home or supper party, with the exception of the wedding cake and champagne. Orangeade or lemonade should be provided for gucsts who do not drink wine. Whatever the nature of the entertainment the bride should put the knife into the cake, of which a wedge should have been previously cut and tied with a bow of satin ribbon to simplify the operation. While more cake is cut, either the chief bridesmaid or the hostess slices the wedge and the cake is handed round with champagne in glasses, so that the guests may drink the bricle's health.

On the buffet all kinds of sandwiches, lobster patties, fancy pnstries, small cakes, fruit, tea and coffee should be set out. Trifles, sundaes, and other ice creams may be also provided. Ahout 4 sandwiches, 1 pastry, and several small cakes can be allowed for each person, while 1 bottle of champagne is usual for 4 persons and 1 quart ice-cream will be sufficient for 12 persons. The buffet should be placed so that the maids who are helping to serve refreshments can pass easily behind it and also have access to the kitchen for supplies. Where there is a service hatch the buffet should be placed in front of this.

Wedding Cake. Bridal cakes are always rich both in their ingredients and decoration. Small silver bells and symbols of good luck are usually added, and occasionally a greeting is written across the top of the cake in icing of a contrasting shade. Many cake shops specialize in making them, but the following
is a good recipe for a home-made wedding cake Cream 1 lb . butter and $\frac{3}{4} \mathrm{lb}$. castor sugar till they are quite smooth; then add 6 eggs, one at a time, and beat thoroughly. Stir in 1 lb . flour. and gradually add 3 lb . currants, $1 \frac{1}{4} \mathrm{lb}$. sultanas, $1 \frac{1}{2} \mathrm{lb}$. finely cut mixed peel, $\frac{1}{2} \mathrm{lb}$. almonds blanched and chopped, $\frac{1}{4}$ oz. mixed spice a few drops of almond essence, $\frac{1}{2}$ gill rum, and 1 tablespoonful dark treacle. Beat well all the time to mix the ingredients thoroughly, nnd then put the mixture into a well-greased cake ring surrounded outside with several thicknesses of brown paper. The cake undernenth must be well protected also. Use a very thick baking sheet covered with sand under the tin on which the cake stands. Bake the cake for five or six hours in graduated heat and keep it for a month at least before icing See page 175 for icing directions and also the entries on Almond Paste and Icing.

To provide a cake of more imposing appearance increase the ingredients in the same proportions to four times the quantities given. Provide two tins, one about 10 in . and the other 6 in in diamcter, prepare them as already directed, and fill them with cake mixture, 3 parts full. Bake the smaller tin for about 4 and the larger for 5 hours on the sand-covered sheet. When cooked allow the cakes to cool and wrap them in white paper for storage in a tin. Ice the cakes when required with almond paste and then with royal icing. Place the smaller cake on the larger before decorating with fancy icing by means of a forcing bag (see page 481), or forcing pipe (see page 617), and completing the whole with the silver ornaments and satin ribbon. On the two ends of the bow the bride's initials can be worked on the left, the bridegroom's on the right, and a spray of white heather passed through the knot.
Wedding Ring. In Great Britain the wedding ring is worn on the third finger of the left hand. For legal purposes the bride has the ring put on her finger by the bridegroom during the ccremony. A widow remarrying usually removes her first wedding ring when she is about to go to the church or register office.

WEDGWOOD : The Chinaware. While old Wedgwood pottery, especially in its more characteristic forms, is not easy to procure the Etrurin factory, established in 1768-9 by Josiah Wedgwood, still produces as vigorously as ever, in some instances from the original moulds, wares which legitimately bear the Wedgwood name.
The term " old Wedgwood," may usually be taken to mean pieces produced before 1800.
These productions are more perfect in finish
than those made during the 19 th century, or even to day, though an excellent quality marks the present output of fine pieces.
The many wares which Josiah Wedgwood invented or improved include the fine creamware which achicved world-wide renown as Queen's ware, the famous jasper ware, black basalts or Egyptian black, several forms of variegated and pebble ware, besides fine red pottery and silver and gold lustre.
The dinner service made for Catherine II of Russia was in Queen's ware. Each of the 952 pieces was hand-painted with a different view of rural England. The black basalt ware, which was solidly black throughout and lent itsclf to finc incised or raised decoration owing to its beautiful texture, is another ware which has been extensively reproduced for Hower bowls and vases.
The distinctive qualities of old Wedgwood are its perfect potting and its fastidious accuracy of detail, extending to the fitting of the lids and the shapes of the spouts. The applied decorations are always sharply defined, the edges bcing undercut and the whole polished on the wheel, resulting in an unmistakable velvety fecl. Queen's ware and pearl ware set new standards of technical excellence which drove out of the market both saltglaze and delft. The early tea and coffee sets in these styles, as well as in basalts and other clay fabries, are highly prized.
Distinguishing Marks. During Josiah's lifetime the mark was impressed in the clay. At first the name Wedgwood appeared alone, but for twelve years after 1768 the partnership mark Wedgwood \& Bentley was used on jasper and crystalline vases except blue jasper, and also upon blue plaques and medallions, on some of which portraits were carried out in relief with exquisite precision of detail. Etruria was added for a brief period after 1840, England being added to meet American requirements in 1891. In 1879 a device of a vase was placed above the name. A threecharacter mark, used since 1846, was definitely established in 1907, when the figure 3 denoted the third alphabetical cycle, and J the letter for that year, preceded by the workman's initial.
The name Wedgwood \& Co. denotes the productions of Ralph Wedgwood, a cousin of Josiah, produced 1796-1800). Wedgwood was used deceptively by Smith, of Stockton, for some ycars, until stopped by a perpetual injunction granted in 1848. Apart from unscrupulous imitations, several pupils and rivals of Wedgwood have produced under their own marks styles of ware created by him, which are also in demand by collectors.

Porcelain made for about ten years after 1805 is distinguished from that produced since 1878 by the plain name Wedgwood, stencilled usually in red over the glaze. In 1848 Etruria took up the manufacture of Parian ware; after 1850 jasper was made with the well-known lavender ground; in 1860 reproductions of Italian majolica were introduced, and some painted ware was done. See China; Jasper Ware; Lustre Ware; Pebble Ware; Pottery; Queen'sWare: Staffordshire Ware.

WEEDS: Their Treatment. Every gardener has to deal from time to time with
weeds of various kinds. They may be annual. biennial, or perennial, and must therefore be combated by different methods according to their habit of growth.

Hand pulling digging with fork or spade and the tota! removal of the weeds are efficient methods of destruction. In every case the weeds collected should be burncd. If these methods are too laborious, owing to the accumulation of weeds, spraying may be tried. Poppies, groundsel, dandelions, and certain other weeds can be more or less crippled and prevented from seeding by spraying them with 25 per cent solution of copper sulphate or a 15 per cent solution of sulphate of iron.
When hand weeding of lawns becomes essential it must be systematically carried out, and clearance should be made square yard by square yard, the labourer kneeling on a pad and spudding out every available weed. Where tap-rooted weeds, or others with large crowns, are rampant, a skewer dipped into a bottle of sulphuric acid will be found a simple eradicator: when using the acid a pair of leather gloves should be worn. To deal with weeds in beds and borders the hoe should be in constant use.
The weeding of paths should be taken in hand during early spring. Hand-picking for such purpose is an antiquated business, whilst the old remedy of applying salt or brine is only effectual up to a point, and sometimes actually encourages a fresh crop of weeds. Proprictary weed-killers, poisonous and non-poisonous, are far more effective, especially when applied on dry, windless, and sunless days. It must be understood, however, that such preparations can only be used for weeds on paths and walks : if the liquid falls on grass or plants these may be destroyed.

Implements Used. Common implements for weeding, usually contained in the average gardener's equipment, are the hand-fork, Dutch hoe, rake, and spud. There are other articles for special purposes, including the daisy rake and certain proprietary tools known as weed extractors. The latter have forks to insert under the crown of a weed, which, by pressure, lift the root stock bodily from the soil. Some instruments are designed for the use of liquid weed-killer. Lawn sand is a preparation made to keep down weeds on lawns. See Dandelion; Dibber; Groundsel; Hoc: Poppy ; Spud.

WEEPING ROSE. A rambler or climbing rose, when budded on a brier 5 ft . or more high, is called a weeping rose ; such a specimen makes a handsome lawn trec. Weeping roses should be pruned as soon as the flowers have faded by cutting out parts of the old branches to make room for the new shoots. All brier shoots must be cut off ; they may develop not only on the stem but among the branches Each tree must be supported securely by a strong stake. Roses which make beautiful weeping standards are Alberic Barbier. Fraicheur, Lady Godiva, Hiawatha, Purity, and Dorothy Perkins. See Rose.
WEEVIL. This is the popular name given to a large number of beetles that have the anterior part of the head prolonged into a beak. They feed upon plants and are injurious to grain. Three types that should be noted by the gardener are the clay-coloured, the black: and the plum weevil ; they appear in late spring and early summer, attacking leaves, shoots, and bark, and causing much damage.
The clay-coloured, or raspberry, weevil is the most harmful of the three and is also the smallest. In habit it is mainly nocturnal, crawling out from its hiding place at night to fecd. It damages fruit blossoms and buds and the tender shoots of raspberries.
The black, or vine, weevil is more troublesome under glass than in the open. In the bcetle stages, it is chiefly injurious to vine shoots and to the shoots and foliage of fruit
trees or shrubs grown under glass. The larva is very injurious to plants in pots, notably to ferns, primulas, and cyclamens. It is not unusual to find six or eight grubs in one pot. The grub is injurious to many garden plants and also to strawberries. The red-legged, or the plum, weevil is a black, shining insect, $\frac{1}{2}$ in. long. It is very injurious to plums and also attacks peaches, nectarines, and apricots.

These weevils are extromely difficult to eradicate once they have become established, and it is therefore of great importance to prevent them from obtaining a foothold. The weevils cannot Hy, and can therefore only reach fresh ground by crawling or being carried in soil when in the grub stage.

In greenhouses devoted to growing ferns or primulas, the first stock should be carefully watched, and if the plants do not thrive the roots of the least healthy should be searched for the white grubs. Potting soil should be examined, and if grub-infested soil has to be used it should first be sterilized by heat.

Young trees and grafted stock can be protected from the adult weevils by banding, since the weevila spend the day in the soil and only crawl up at night. Apart from this, the only treatment is to catch the weevils at night by shaking them on to tarred trays or boards. Vast numbers can be caught in this way, but care is necessary, as the insects fall off readily when alarmed. No insecticide has proved of any use against them. See Apple Blossom; Gall Weevil ; Grease : Plum
WEIGELA. The bush honeysuckle, ca!led the weigela, is a beautiful, hardy leaf-losing shrub, 5 ft . or more high, which blooms in early summer and thrives in ordinary well-tilled land. The typical kind is rosea, with rose-coloured blooms. Improved varieties are Eva Rathké, crimson; Abel Carrière, rose crimson; Mont Blanc, white, and Van Houttei, rose and white. Propagation is by cuttings of young shoots under glass in May or by inserting woody cuttings out of doors in autumn and covering them with a handlight.

WEIGHT. The weight of an individua' depends on the height, age, and sex. The ratio of weight to height varics considerably in healthy people. The average weight for a man and woman about 25 years of age, and of a height of 5 ft . and over, is as follows
A few 1 b .
must be added for very addiional 10 years of age, more for a woman than for a man. If the weight of an individual is $1 \frac{1}{2}$ or 2 st. below the average for his height, and more particularly if there is a

|  | 13 | - |

loss of weight, there is need for a thorough overhaul by a doctor.
WEIGHTS AND MEASURES. In English law all weights and measures are based upon the pound and the yard, which are the only independent standards. The gallon, which is the standard of all measures of capacity, is based upon the pound. It is defined as the volume of ten standard pounds of distilled water weighed in air against brass weights, both water and air at the temperature of $62^{\circ} \mathrm{F}$ with the barometer at 30 in .

Legal Points Certain commodities have conditions about their sale. Coal must be sold
by weight tor domestic use. Where the quantity exceeds 2 cw ., the seller must deliver to the purchaser a weight ticket showing the net weight of the coal delivered before any part is unloaded. The sale of coal in quantities not exceeding 2 ewt is governed in most towns by the by-laws.

In selling any article of food by weight. measure or number, it is an offence to deliver a less weight, measure or number than is purported to be sold Tea, coffec beans, cocoa and potatoes must be sold by net weight. Certain other articles of food may be sold with the wrapper included, provided the weight of the wrapper does not exceed certain specified amounts. In the case of meat it is an offence to deliver to a purchaser any butcher's meat without a legible statement of weight upon which the purchase price is based, unless the delivery is made to the buyer on the premises of the seller immediately after the purchase has been made

If the meat is boned or trimmed and such boncs and trimmings are not delivered with the meat, the delivery note should then contain two statements of weight, (1) the weight on which the purchase price is based, i.e. before boning and trimming, (2) the net weight as sent out. All bread, excluding fancy bread, must be sold by net weight and must be made in weights of 1 lb or an integral number cf lbs.

No milk must be sold in bottles or containers except in quantities of $\frac{1}{2}$ pint or multiples of $\frac{1}{2}$ pint. This does not apply to dried or condensed milk. See Avoirdupois Weight: Bushel; Decimal System; Dry Measure; Gas; Liquid Mcasure: Measurement: Metre; Ruler: Therm; T Square, etc.

WELDING. A simplified process of welding or uniting ferrous metals consists in heating the parts to a white heat, placing them one upon the other, and hammering them into union. Autogenous welding has to a large extent taken the place of the older method, especially for small work. The apparatus consists of a blow pipe with oxygen and acetylene gas under high pressure. These gases are mixed within the blow pipe and cmerge at a high velocity from a small nozzle. Ordinary welding can be carried out by the a mateur, but considerable practice is required. Success depends on the proper heating of the metal, the direction of the hammer blows, and often the use of a suitable flux placed between the joint faces in order to assist adhesion.

While the practice of welding is generally limited to the ferrous metals, it can be employed with modifications for some others. Autogenous welding is particularly applicable to articles made of cast iron, which, by their nature, cannot be united by hammering. See Brazing; Flux: Forge: Metal Work; Soldering.

WELL : For Water Supply. In country districts the water well is vitally important, and it is necessary to give much attention to the subject when considering the purchase or renting of a country property.

There are several methods of ascertaining whether water is present bencath the surface. One is to employ a water diviner, who, with the aid of a hazel twig, is able to locate running water with considerable accuracy. A more scientific method is to use a regular waterdivining instrument or to call in a geological expert.

Although the diviner is able to say that water is present, it is impossible to krow whether it will be fit to drink until it is actually reached. Consequently, before incurring the expense of making a well, the surroundings should be carefully studicd. If stables or cowsheds are in the vicinity and on land slightly higher than the site of the well,
there is risk that the water may he contamin ated, and it is better to fincl another site.

When there is any choice in the matter, the most convenient site will be that which is highest in respect to the bnilding to be supplied with water, and also nearest to it, if about the same level. In hilly distriets there is often no nced for pumping water, the spring being at a sufficient altitude above the house. Such ideal conditions, however, are seldom realized in the more level parts of the country, and some means of mechanically raising the whter from the well is necessary

The plan commonly adopted is to employ the local well-digger to dig the well and to brick it up on the inside. An alternative plan is to use well-boring tools, boring only a small hole, perhaps 4 to 6 in in diameter, and sinking an iron pipe into the earth, but this is only practicable when the pipe would terminate in a stratum yielding a sufficiently voluminous supply, or when an attesian well can be madc. See Pump: Ram: Water.

WELSH CAKE. This refers to a currant cakc mixture made as stiff as short crust, rolled out into a sheet, and then cut into rounds with a cutter or the lid of a tin. These rounds are bated on a lightly greased girdle or bake-stone.

Take l lb. flour, a good teaspoonful of haking powder, a pinch of salt, 6 oz . lard or laril and butter mixed, 4 oz . castor sugar, 3 oz. currants and sufficient milk to mix all to a stiff dough. Sift the sait, baking powder, and flour togetlier, rul in the fat, add the sugnr and currants, and moisten with the milk.

Roll out about $\ddagger \mathrm{in}$. thick, cut into ciakes, and trake on the bake-stone. Turn the cakes when browned one side and brown the other side. 1 or 2 eggs may be added if a superior cake is required, but less milk would be noeded in that cease. Sour milk or butter milk improves these cakes. They are generally eaten hot for tea. See Girdle.

WELSH CORGI. This dog is regarded as having two centres of origin, namely, Pcmbrokeshire and Cardiganshire. The distinctive feature of the two is whilst the former have long tails the latter have short ones. Moreover, the Pembrokeshies variety are either red or red and white, whereas tne Cardiganshire dogs are any colour excepting white, and the latter are slightly heavier. The weight of the corgi is from 18 to 25 lb . The head is foxy and the ears erect or semi-ercet. The contour of body is also foxy, but the limhs are of sturdier build than that of the fox. The coat is smooth but harsh. Corgis make excellent workers for sheep and are good tempered and hardy.

WELSH DRESSER. This name is given to a picce of furniture that was made in Wales, the reason presumably being the abundance there of oak. This type of dresser is made of oak, frequently with a simple inlay of mahogany. It is polished dark, has plain rectangular mouldings, and also plain brass droppers for tho drawers.

Pieces labelled by the name Welsh dresser are often spurious. A useful test is the condi-
tion of the brass. If the piece is a genuine antique, time will have browned the handles : consequently those that look new should be suspected. See Dresser.
WELSH OMELETTE. Wash three small lecks, taking care to free them from grit: trim off the root ends and most of the green portion, and then cook them in stock or water until they are tender. Drain them, cut them into thin slices, and mix with a little butter and dust with pepper. Keep hot while making a plain omelette, and put leeks on one half and fold over. Sometimes a little grated checse is added. See Leck ; Omclette.

WELSH RAREBIT. A rich cheese such as Cheshire or Cheddar should be employed when making a rarebit. Glouccster chcese is sometimes substituted for Cheddar. Cut up 4 or 5 oz . cheese in thin slices and place them in a saucepan with 1 oz. hutter, 1 small mustard-spoonful made mustard, 3 tablespoonfuls draught mild ale, and scasoning of cayenne pepper and salt.

Stir the cheese over gentle heat until it is melted and the whole has the appearance of a creany mixture, then dish it immediatcly on hot buttered toast. The toast must be freshly made and the crust cut off, also it should be crisp and evenly browned, although not hard. Rarebit requires speedy preparation, and it must be served immediately it is cooked. Malt vinegar may be added instead of alc.
A second method consists of flaking into a small pan 5 oz . checse, adding $1 \frac{1}{2}$ oz. butter, a good pinch pepper, salt, and a small quantity of dry mustard. Stir these together and melt them in the oven, then serve on toast. Sometimes 2 tablespoonfuls milk are added to these ingredients before putting them in the oven.
WELSH TERRIER. Probably similar in origin to the wire-haired fox terrier, the Welsh terrier has the same sporting instincts and the desire to exterminate all four-footed vermin. But, as in the case of the fox terriers, this does not unfit him for human companionship, and he will be found to be a good house dog. of affectionate disposition, and not apt to quarrel with his own kind.

In many respects similar to the wirehaired terrier, his head is rather wider and the muzzle more powerful. He has a very close and abundant coat of hard, wiry hair of black and tan or grizzle and tan, without any black pencilling on the toes. The height at the shoulders should be about 15 in ., and weight about 20 lb .; less in each case for the bitch. See Dos.

WEST HIGHLAND TERRIER. This rather small but strongly built. hard-coated dog is often regarded as a white variety of the Scottish terrier, but it is a distinct and ancient breed, kept up for routing the fox, otter, and badger from their Iairs in rocky ground. To indomitable courage are added great intelligence and devotion to his owner. For the show bench he must be wholly white with the exception of his nose, his footpads and nails, which are black, yet he may be quite true to type even if he has a little red or yellow on his back or ears. He stands from 8 in . to 12 in . at the shoulder, and weighs

West Highland Terrier, a breed of small sporting dog which combines great courage with affection
not more than $18 \mathrm{lb} .$, the bitch 2 lb . less. There is a soft, close, furry undercoat, im pervious to wet. See Aberdeen Terrier; Dog.
WHAT-NOT. This term is used for a piece of furniture, something resembling a cabinct without doors, that was very frequently seen in English houses in the 19th century. It is made usually of slender pillars or uprights that support a number of shelves, suitable for displaying china. What-nots are made chiefly of walnut and mahogany, but the most decorative examples were of papier mâché japanned black, painted in Horal designs and often inlaid with mother-ofpcarl.

WHEAT. Most of the flour which is used in coolsery is produced from wheat, though cornflour, rice flour and maize flour are also employed. Flour varies in quantity, wheat that possesses a low percentage of gluten yielding soft flour, and that with a high proportion, a hard, strong flour that develops elasticity when mixed into dough. The colour of flour also depends upon the wheat from which it is obtained. White whent produces a pure white flour and red wheat a flour that has a yellowish tinge. See Flour.

WHEATMEAL BISCUIT. To make these, sieve $\frac{1}{2} \mathrm{lb}$. wheatmeal and one teaspoonful ground ginger into a clean, dry basin, rub in a lump of butter about twice the size of a hen's egg, and then add two tablespoonfuls sugar. Stir in first a beaten egg and then cnough milk to form the whole into a stiff paste; roll the mixture out on a floured board until it is about $\frac{1}{8}$ in. thick, and cut it into biscuits, baking these in a moderate oven until cooked through, and lightly browned.

WHEEL. In this Encyclopedia dif. fering types of wheel are dealt with under such headings as Bicycle; Gear; Mangle; Perambulator; and Scwing Machine. Change whecls used on the screw cutting lathe are described in the articles Lathe and Metal Turning. For hints on repairing whecls of toys sec the article Toys.
The road whecls of the motor vehicle arc dealt with in the contribution immediately follow. ing, and other information will be found in the articles on Cotter; Motor Car; Motor Cycle: Sprocket: Tire.

## WHEELS FOR MOTOR VEHICLES

## Modern Tendencies in Design and Construction

## Other articles in this work that are of interest to the motorist include Motor Car; Motor Cycle and

 Motoring. See also Brake; Gear; Tire; TransmissionConsiderable changes in wheel construction have occurred during the last few years as the result largely of the introduction of largesection low-pressure tires the use of wired or straight-sided tires instead of bcaded tires, and the substitution of pneumatic tires for solid tires on commercial vehicles. Overall diameters of tires have not increased: the tendency is in fact in the reverse direction and wheels have become smaller and lighter.

Motor-car wheels carrying pneumatic tires may be classified broadly as spoke, wire and disk. Further, the design depends upon whether the wheel is detachable as a whole or whether only the rim with the tire is detach able from the wheel. A complete fixed wheel with detachable rim is heavier than a detachable wheel carrying the same size of tire. Also in the event of accident such as a wheel striking the kerb, a fixed wheel, if broken, will disable the ear completely, whereas a detachable wheel may bend or collapse without damaging the axle, so that it is only necessary to fit the spare wheel. The detachable wheel is generally used in Great Britain, while the detachable rim has been used largely in America, but is now yielding place to the detachable wire or disk wheel. The steel spoke wheel after many years of popularity has to some extent yielded precedence to the wire wheel with a well-type rim on ordinary motor cars and on the lighter commercial vehicles, but special disk wheels with flat base rims are largely used on the heavier commercia vehicles. Such wheels have largely replaced cast steel wheels with solid tires. In the ordinary motor-car industry changes in the popularity

Wheel for Motor Vehicles. Fig. 1. Steel detachable spoked wheel with brake drum and hub cap
of different types of wheel are often due to fashion rather than to technical superiority.

Wooden wheels with detachable steel rims are still largely used on American cars, these wheels being of the artillery type ; that is, the inner ends of the spokes are clamped between two circular steel plates forming the boss or nave. The circular rim or felloe (pronounced felly) is of wood, with a light metal rim which supports the steel rim carrying the tire. This type of wheel was long ago superseded in Great Britain by detachable steel wheels of similar appearance but of radically different zonstruction, the Sankey steel wheel shown in Fig. ] being an example of this type. The drawing shows a

Fig. 4. Heavy disk wheel as used with giant
light sheet-metal plated cap N with a flanged edge entering the recess. Spring-pressed plungers 0 on flange retain the cap in position.

Detachable disk wheels consisting of a stcel rim riveted to a slightly coned disk are much less used to-day than the other types on ordinary cars, but a similar appearance has been obtained by securing light conical disks on the outside and inside of wire wheels. Apart from the matter of appearance, these disks reduce the labour of washing the many wire spokes and thus remove the most serious disadvantage from which wire wheels suffer in comparison with other types. Modern wire wheels are. however, constructed with a smaller number of thicker spokes more widely spaced, so that the cleaning difficulty is thereby reduced.
Although not very popular on passenger cars and light vehicles. specially designer disk whecls are widely em. ployed on the heavier commercial vehicles, a Sankey wheel being shown in Fig. 4. The rim of this wheel is of the flat-base type as distinct from the wellbase type, but it carries similar wired or straightsided tires of large size known commercially as giant pneumatics. A disk $P$ is secured to the end of the axle by a number of studs and its outer edge is flanged and is riveted to a rim having an integral flange Q on one side. The other

also coned to bear against a cone G on the axle. The coned surfaces are pressed into engagement by a lock nut H with two ears, which may be tightencd up by a lead or raw hide hammer or a wooden mallet, but not by a metal ham mer. The lock nut screws on to the axle and is formed with a double conical recess $J$ which engages the end of the hub and is thereby locked securely against rotation, no other locking arrangements being necessary.

A modified type of wire wheel which has recently attained considerable popularity is secured to the axle by a number of studs and nuts as in the Sankey wheel described above, but the nuts are located inside the hub and are concealed by a large plated cap. A RudgeWhitworth construction is shown in Fig. 3. The large steel hub K, although very strong, is made of comparatively thin metal and is secured by wire spokes to the rim, many of these spokes being arranged tangentially to the hub so as to transmit the driving and braking forces. The inner face of the hub is secured by studs and nuts against the outside $L$ of the brake drum, the nuts M being rotated by the usual wheel brace. The opening on the outside of the hub is large enough to give proper access to the nuts and is closed by a

Wheel. Fig. 2. Detachable wire wheel with central locking nut. Fig. 3. Detachable wire wheel with studs and securing nuts concealed within the bollow buh by a covering disk
lange $R$ by which the tire is retained in position, is formed by a detachable rim held in place by a spring ring $S$.

With all types of wheels care should be taken, when placing thein in position, that the engaging surfaces are clean and free from mud or grit which might prevent them from being clamped up firmly.

WHEELBARROW. The wheelburrow is extremely handy for conveying all sorts of garden material. As it is easily tipped either sideways or on end, its contents may be shot at any point

## desired

without the
necessity of Fig. 1. Hand barrow consisting handling them of a flat shallow tray with four A hand barrow
is also useful, but needs two persons to carry it. In its simplest form (Fig. 1) the hand barrow is a flat, shallow tray fixed to two lengths of wood which are formed with handles at each end, where they project beyond the tray. Four legs enable the barrow to rest conveniently on the ground.
The wooden barrow shown at Fig. 2 can be easily made. The wheel, generally a stumbling point with the novice, is not difficult to construct, and when hooped it is quite satisfactory. The strines, or handles, should be of ash or oak; the mortise holes are bored out and then cut with the chisel to the sizes shown at Fig. 3. The sloats, or cross rails, made of oak, ash, or elm, are 3 in . wide in the centre, tapering to $2 \frac{3}{4} \mathrm{in}$. at the ends They thus form a wheelwright's self-wedging tenon.

Begin by making the barrow frame, as shown at Fig. 3 ; then fix the two legs F, by securing them with a long $\frac{3}{8} \mathrm{in}$. or $\frac{1}{2} \mathrm{in}$. bolt, which should run right through the frame and be secured with a washer and nut at the other side. This bolt and the hoop and axle

will coincide with the angle point on the cross rails Set out the ends of the cross rails and cut the tenons with bevelled shoulders, as shown at Fig. 4. The bevelled shoulders make an angle of $45^{\circ}$ with the edges of the cross rails. The next stcp is to slot mortise the rim rails $A$ to fit the tenons, knock them up in their positions, and again mark out the complete circle. Take the rails $A$ off the cross rails and saw and
will be all the metal work required from the local smithy, as all other portions are of timber

Fix in the bottom of the barrow out of ${ }_{5}^{5}$ in tongued and grooved boarding bottom portion is nailed on to the sloats: it hangs over the wheel about $\frac{1}{2}$ in. and over the handle sloat 1 in. Select suitable boarding for the barrow bottom before setting out for the mortisc holes. The worker will then be able to arrange for the sloata to stand down below the top edge of the strines exactly the correct thickiness of the bottom boarding
The two brackets B are now lixed in position by skew-nailing them from the top, as shown in the detail drawing, and putting a gond nail or screw from the under side of the strine The front piece $\mathbf{H}$ is planed slightly on the bevel at its bottom edge and nailed on to the brackets B. Next take the sides $G$, hevel the bottom edge so that it beds on the strine, whilst its side leans out. wards and berls on the leg F . When the siles are fitted in a satisfactory manner, nail them to the leg F from the inside of the
barrow, and nail their ends which engage with the front board $\mathbf{H}$ by nailing from the front of the barrow Fit the piece J, and nail it to the ends $H$, after which fix the brackets C . The piece D, which steadies the legs, is now nailed in position.
To fit L, take a piece of wood, about 6 in longer than you think will be required, and plane its edges ao as to bed against the side $G$ and the front board $H$. When neatly fitted to the required angle, sketch a line with your pencil to what appears to be the correct angle that will fit the strine. Saw the piece $L$ to the sketched line, and, holding it to bed against the barrow side and the front, slide it down and sec if it makes a good joint with the strine. It will probably be alightly out, but it will enable one to see the exact part that requires paring off with the chisel. Repeat this "cut-and-try" method until the desired joint is obtained, then cut off the surplus portion at the top of piece L , and nail L in position to the strine, front, and the side Ease off the corners of H and G, as shown.

Making the Wheel. The wood for the wheel should be of ash or oak. Plane up the two cross pieces and halve them, as shown at Fig. 4 Find the centre and mark out the diameter of the wheel: the circumference of the circle

Wheelbarrow. Fig, 2. Useful garden barrow which can be made at home. Fig. 3. Plan of frame and dimensions of the detail parts which are necessary for constructing the wheelbarrow shown in Fig. 2, Fig. 4 Showing method of constructing the wheel
spokeshave them to the required line. Fix
the wheel together by smearing the joints with thick paint and put a fine nail in the joints, so as to hold all together until the blacksmith hoops the wheel. A square hole is cut through the centre of the wheel after it is hooped; the axle is driven into this mortise and the wheel secured by a washer and nut
The small axle brackets K are bored only half-way through their thickness, and this hole receives the axle. These brackets should be of hardwood, such as ash. The brackets B and K are held at the front with a $\frac{3}{8} \mathrm{in}$. bolt and nut, which goes through the strine. The other end of bracket K is secured with two wrought-iron rails. Finish barrow with three coats of dark green paint.
The following particulars will assist the worker:
Whecl, all of ash, 2 in. thick, or, say, $1 \frac{1}{8}$ in. finish ; legs, ash or oak, $2 t$ in. qquare at liottom

Brackets, B, C, and D, English clin, 14 in thick
Sides (G), front (H) and back (J) of clin or other
vood, such as white deal, 1 in. thick
Brackets (K). ash, 18 in thick
Strines, English ash, size is drawing
Piece L, Heh or red deal, 1 in. by if in
Barrow hottom. elin, ach, oak, or deal, about \& in. or 4 in. thick, made in one piece or tongue-and-groove jointed

Many workers leave the sides, back and front boards roughly sawn with their ends
square until they are fitting their worls The overhanging portions of H and $J$ ar afterwards cut off to the required bevel, which will be proved by nailing on the sides. See Chisel; Joint; Mortise; Plane, etc.
WHELK. The small shellfish linown as a whelk has a twisted shell of a conical shape. There are several varicties, the ribbon, the red, and the dog whelk, all equally indigestible. Nevertheless, the whelk is eaten in the same vay as a winkle. See Shell lish
WHETSTONE. Used for sharpening scythes, hooks, axes, and other cutting tools, whetstones are made from stone, emery and carborundum, and in shape are either round or Hat, the former being smaller at the ends than in the centre. Gencrally a coarse stone is employed without a lubricant; those with a tine grain, especially if made of carborundum. should be used with a thin mineral oil.
To sharpen a tool, the side of the stone is placed Hat on the blade and moved along with a spiral motion. keeping it flat against the blade and placing the correct amount of pressure on the down stroke; the up stroke should be as light as possible to prevent the formation of a wirc edge. The whetstone should be kept quite dry when not in use. See Grindstone ; Hone ; Oilstone.
WHEY. The watery liquid that is known as whey, which remains in milk after the separation of the curd by coagulation, is composed of water and lactic acid with a sinall proportion of casein and butter and sometimes cream. It is used for making certain drinks, and is valuable also in intlammatory complaints. Rennet is used in producing whey, but there are several other methods which can be employed.
For whey with curds soak a small piece of rennet in $\frac{1}{2}$ teacupful warm water and let it stand 2 hours. Pour I dessertspoon. ful of this liquid into 2 pints boiling. milk and lieep it warm but not hot until the whey begins to separate and looks clear. This dish is the old-fashioned curds and whey and usually is eaten with crean and sugar. Prepared rennet may be used in place of soaking a piece of rennet from the calf.
To make lemon whey, pour as much of the strained juice of a lemon into $\frac{1}{2}$ pint boiling milk as will produce a curd. The whey is then strained off and sweetened. Whey is sometimes flavoured with mint or other aromatic herbs and taken as a summer drink. It is not lowering like some of the acid preparations. Pigs are fed occasionally on food mixed with whey and are then termed whey pigs. See Cheese ; Junket; Rennet.

WHIELDON : The Ware The Stafiordshire earthenware produced at Fenton by Thomas Whieldon for about 40 years after 1740 is in demand by collectors. It is of interest in association with that of Spode, Wedgwood, and other 18th century potters.
Whicldon ware consists largely of the variegated or clouded pottery which preceded the great developments of creamware and jasper, especially imitations of agate and tortoiseshell, as well as those based upon the forms and colours of caulitlowers, maize, pineapples, and melons Especially prized are handsome octagonal plates finely mottled, with purplish browns, yellows, and greens, and old Staffordshire pieces of this type, when not otherwise identified, arc usually classed as Whicldon. His earliest pieces were agate
knife-handles and snufl boxes, now rarely met with except in spurious inita tions Other classes com prised tea, chocolate and coffee pots in a fine black ware which was the preoursor of black basalt ware.

Although the greates part of Whieldon's output consisted of useful articles, he also turned out image toys and chimney ornamentsafter the style of the exampleillustrated. Whieldon's saltglaze pieces of this type are often called Astbury figures, theconfusion being aided by the circunstance that neithei potter made a systematic practice of marking his name. The two malies can be distinguished by the fact that Whieldon did not use red or brown clays, and his bodics are usually harder than Astbury's.

Much so-called Whieldon ware probably includes pieces actually made by Wedgwood, l3ooth Warburton, Ralph Wood, and others. He was especially fond of modelling animals, including clephants, squirrels, parnkeets, nnd poultry; in addition, groups of musicians and mounted soldicrs are found in his pieces. See Pottery; Wedgwood

WHIPPET. Although this hreed was brought into existence by the colliers in the N. of England especially for the purpose of coursing rabbits, the whippet, or snap dog, has always bcen accustomed to a domestic life, and is an affectionatc compnnion. The coat may be of almost any colour-black, white, red, tawn. brindle, blue, or a mixture of any of

Whippet. Champion of this sporting breed
them. In size he is variable, but should be about 17 lb . in weight, the bitch a pound or so less See Dog.

WHISKY. Whisky is a spirit distilled from grain. It is made from malt, mnlted barley, or from a mixed grist of barley inalt and dried barley and oats or from a mixture of other malted and unnialted cereals.
Pure malt whisky is made almost exclusively in Scotland. Irish whisky is made of about $\frac{1}{3}$ malt to $\frac{3}{3}$ oats and maize; it neerls longer cepping than Scotch whisky and should be at least 10 years old. Blending and diluting take place in the bonded warehouses. Whisky, like brandy, is naturally white, and takes its colour and, to a certain extent, its Havour. from the sherry casks in which it is matured It is also coloured by the addition of caramel (burnt sugar) or adding a matured wine. The older whiskies were darker in colour from. being

kept in golden sherry or Madeira casks, and rather heavier in texture. The newer whiskies are lighter and drier in taste.
Medicinal Value. Whisky has merlicinal valuc principally for chills, fevers, colds, intluenza, and malaria. As a heverage. diluted with plain water or with mbineral water, it can be taken by gouty and rheumatic people when wine is not advisable. It is important to note that whisky should not be drunk with oysters or any hind of shellisish. See Alcohol; Brandy ; Stimulant.

WHIST. The game of whist is played by tour persons, two against two, although there are variants of the game suitable for two or three. Two paclis of cards are clesirable, onc being used in dealing by each sirle. The players cu. for partners. the two who cut lowest playing against the two highest, and the lowest of all deals first. In these cuts the ace counts as the lowest, not as the highest, card. If two players draw cards of equal value, not being the two highest or the two loweat, they must draw again

The cards should then be shuffled, cut, and dealt. the shuffling being done by an opponent of the dealer and the cutting by the opponent on his right. The deal begins with thr: player who cuts the lowest card, afterwards passing to the one on his left, and so on mntil the end of a rubber, when the procedure begins nll over again. In case of a misdeal the carcls nust be shuffled and dealt again. The full pack is used, nnd all the cards are dealt out, I3 to each player:
The four cards that are played out in a single round form a triek, and this is taken for his side by the player who plays the highest of its four cards. Players must follow the suit led, whenever possible, and the highest card of that suit wins, ponvided it is not trumped. The trump euit is decided for each game by the last card dealt out, this indicating the trump suit. This should be laid upon the table face upward, by the denter and left there untit the first round has been played, when he talies it up.
Seoring. A game consists of live points and a rubber of three games. A point is scored for every trick made in excess of six. Thus if two players win nine tricks they score shrec points. If the same players win the first two games it is unnecessary to play the third Honours may be scored. They are ace, king,
queen nid knave, but not ten, ae at bridge. If two players hold in one hand or in two the four honours they score four points; if they hold three they score two. Those players who, at the beginning of a deal, have a score of four cannot score honours.

The winners score two points, in addition to the value of their games, for winning the rubber. They also score a treble, or game of three points, when their opponents have made no score; a double, or game of two points, when their opponents have scored one or two: and a single, or game of one point when their opponents have scored threc or four. If the rubber has gone to the full threc games, the final score is male by deducting the value of the game won by the losers from the gross number of points made by the winners.

For revoling, or playing a card of a differeni suit when holding one or more of the suit led, the penalties are: The opponents, at the end of the hand may either take three tricks from the revoking player and add them to their own tricks, or deduct three points from the opponents' score, or add three to their own score. This penalty can be claimed for as many revokes as occur during the hand, and a different one may be exacted for each revolie. The penalty, however, cannot be divided.

Cards must be placed on the table, or exposed, under the following couditions: If two or more have been played face upward at one time; if a card has been dropped, face upward, in any way on the table, even though it has been picked up again so quickly that no one has really scen it ; nnd any card that the player holding it has named. The exposed cards must be left on the table and can be called, or played, by the opponents at any time. If two or more cards are played at once, the opponents have the right to call the remainder. It should be noted that a card does not hecome an exposed card if it is dropped on the floor or clsewhere beneath the table

Whist Drive. Although hridge has supplanted whist as the popular card game, $n$ whist party or drive on the progressive principle is sometimes hcld in connexion with clubs of all kinds, and sonuctimes as a means of raising moncy for charitable purposes. In the latter case persons buy tickets in order to attend. At all kinds of whist drives it is usual to give prizes to those who score the greatest number of points. There may be one, two, or more prizes for men, and the same for women.
The hostess should lirst decide how many persons she can accommodate or proposes to ask, and should then send out the invitations. The number invited must be a multiple of four, and if any persons refuse their places must be filled, unless the refusals happen to number exactly four or eight. Women and men should if possible be equal in number. Sometimes the bostess does not include berself in the number of players, and so is able to fill a vacancy if one arises at the last minute.
On entcring, each guest is given a card, on which the scores will be entered. This bears also a number indicating the table at which the player vilil play first. The four players at cach table cut for partners. One game only is played before the players move on. Each player puts down on his or her card the nuwber of tricks scored, and has it initialled by his or her partiner.

The usnal plan is for the winning lady to go forward, that is to go from table 4 to table 5 , for example, and the winning man to go back: ward, i.e. from table 3 to table 2. Other arrangements, however, are sometimes made, this matter being decided by the hostess beforehand. Half-way through the programme refreshments should be served. Thus, if an evening's play consists of 24 games, refreshments will be taken after the completion of the twelfith. At the end of the play each player
adds up his or her score. and the host on someone clsc asks for high figures, say, in excess of 100 . Eventually he gets to know the highest scores, and, having examined the cards, announces the winners. The prizes, provided by the hostcas, are then giren awny. At some whist drives a hoohy prize is given for the owest score, for instance, a wooden spoon.
In order to break the monotony of the scoring, rarious devices are introduced into the programme, and these are usually indisated on the scoring cards: if not, they can be announced hy the host. For instance, in one round, instead of trumps leeing decided by a turned-up carl, they are fixed at a certain suit all over the room, e.g. clubs. Again, the winners in one round are pllowed to score double, or for a change each pair is credited with the score of the opponents, thus inaking the particular game one in which sach ainas at making as few tricks as possible. See Bridge Party; Evening Party : Progressive Party

WHITEBAIT. When in good condition, whitebait, which are the fry of sprats and herring, have a silvery sheen. They must be eaten aoon after they are caught. They should be kept on ice until time for cooking. Whitebait are in scason from March till September.

The fish must be handled as little as possible and the fat used must be at the exact heat neces. sary to crisp them. Drain the whitebait in a clean cloth and see that all the water is absorbed, then turn them on to a Houred sieve. dredge them with Hour, and shalic them gently.

Have the fat heating ready for tho whitebait, and when it reaches 4) $0^{\circ}$ turn the prepared fish into a frying basket and plunge them into the boiling fat. Fry for 2 or 3 min., turn the fish on to a sieve to drain and serve very hot. They should be dished on a folded tish napkin and aprinkled well with salt. Cut brown bread and butter, quarters of lemon, and cayenne pepper should be handed round.

To devil whitebait prepare as above, then scason with cayenne pepper, raise the temperature of the fat rather higher than it was for the first time of frying, and plunge the fish into the fat, and after 1 min . drain, season, and serve very hot. See Fish.

WHITE CURRANT. The white or pale yellow currant is less commonly planted than the red varieties of this popular bush froit. It needs exactly the samc treatment as the red currant. Some of the hest varicties are Whitc Dutch, White Transparent, and White Versaillaise. See Red Currant.

White Lead. See Paint. WHITEMICE. The albino and the black-eyed white mice thrive in captivity if kept in a clean, dry cage and fed once or twice daily. Apart from a little vegetable food and brend soaked in mill, the stock food is composed of equal quantities of canary seed, nillet seed, and oats, the daily allowance being a small teaspoonful per head. The cage must be cleaned very thoroughly three times a week and food pans must be kept scrupulously clean.

Mice should always he kept in couples, as they do not thrive singly. If several are kept in one cagu, care should he taken that there is only one male. If a litter is expect rd, a small supply of clean hay should be provided and the doe removed to a separate cage. Mice should

White Currant.
variety known as $\begin{gathered}\text { Ripuit of the }\end{gathered}$ Dutch
he lifted up by grasping the tail firmly about. half-way up. The best covering for the floor of the cages is dry sawdust mixed with a little sanitas powder.
WHITENING. The name of whitening or whiting is usually given to the well-washed residue of chalk. It should form, when crushed. a tine powder. and when placed in water should separate into fine particles at the bottom of the vessel and is not soluble. It is used for many purposes in the workshop and the home. In making whitewash it is mixed with size ; it is used for polishing and it forms the basis of several linds of wood-filler.

## White Sauce. See Sauce

WHITEWASH. Whitewash is usuallv a mixture of slaked lime and water. Whitening is also used. The ingredients that are required for internal work are the whitening, some size, and a little ivory black or blue to keep the colour white.

To prepare the whitewash, break up a guantity of the whitening, say, about 6 lb ., in the pail, which should contain sufficient water to cover it. Allow the whitening to hecome thoroughly soaked or dissolved, and pour off any surplus water. Having stirred it, add a quart of hot double size, previously prepared. The mixture is then given a thorough stirring. and set aside to cool, when it will form a jellylike compound. Blue or other material should be added at the same time as the size.
When required for use, the mixture is diluted with cold water and applied immedintely. For exterior work ordinary lime may be used as paste and sufficient of ihis used with water to form a thick liquid. The fraste is best kept in a box or pail sank in a hole in the ground and covered with water to keep it from drying. When required for use, the water is poured off and the lime, a smooth, white mixture, is emiployed.
Whitewash or limewash made in this way can be applied dircetly to the exterior surface of brickwork with a large, old whitewash or distemper hrush, one good coat being usually sufficient. It should not be applied too thickly or it will be liable to flake off, nor should the mixture the too weak or it will not dry with a clear surface. If the brickwork has not previously been whitewashed, it should be brushed down with a stiff bristled brush. If the surface has already been whitewashed, it is desirable to wash it down with copious supplies of water and brush it thoroughly.

Ceilings. To whitewash a ceiling more preliminary preparation is necessary, cither covering the floor with old newspaper or clust shects, or entirely removing the lloor covering. All small furniture should be placed in another room, the larger pieces being assembled in the centre of the room or in any other convenient position and covered with dust shects. To keep
the whitew ash from spatterthe whitellash from spattering over the hoor and the
walls, it is a good plan to fix walls, it is a good prant covering over the walls, or at least those portions where whitewashing is in progress.

The whitewash is then prepared as already described. Another pail or bucket tilled with clear water will be needed for the preliminary washing down, which simply consists of brushing the ceiling vigorously with a disused whitewash brush. This re-
previous coat of Whitewash. The ceiling is allowed to dry, and if very good results are required it may be covered with clearcole, a thin liquid obtained by dissolving some size and a sinall quantity of alum in hot water and adding a little whiting. When brushed over the ceiling, this stops the suction and makes the whitewash take better, but it is often omitted on ceilings in good condlition.

As soon as the clearcole or the washing off is dry, any cracks are made good with Keen's cement or a plaster, and the whitewashing proper is commenced. It ought to be continued uninterruptedly until the whole of the ceiling is linished. The work should commence at one corner of the room and may include the cornice and frieze, if desired. The whitewash can probably be applied by the amateur to the cornice and mouldings with a small brush, but the bulk of the ceiling is best dealt with by the large distemper brush.
There is a knack in applying whitewash which it is not easy to describe. The cssential thing is to charge the brush with suflicient colour to enable the largest area to be covered without refilling the brush. To do this the brush must be immersed fully in the whitewash; any surplus is wiped off by stroking the brush on the edge of the pail, any surplus at the tip being similarly wiped off on the ellge of the pail or on a bar placed across it. Under thesc conditions, the brush will be found to hold a considerable quantity of whitewash. which may be applied to the ceiling with n kind of slapping and stroking motion. In a sense, the whitewash is Hicked on the ceiling on the first part of the stroke, and the other part of the stroke is a smoothing operation.
Whitewash is practically transparent while it is wet. The quantity that is applied can be judged by the feel of the brush while it is being wiped over the surface of the cciling. At the first application of the brush the feeling is that there is too much of the lluid, whereas towards the end of the stroke there is a drag. The correct quantity is that which is applied when the brush is ahout half full. The manner in which the brush works then should be taken as the standard to be adhered to throughout.

WHITEWOOD. The timber that is known as whitewood is really spruce. It is less stmang and durable, and therefore less suited for outdoor work, than is red timber, but has a number of indoor uscs. When emploved for joinery purposes it requires keen tools for its proper manipulation, but when it is tinished it presents a fine lustrous surface with a creamy colour. It thus forms an excellent material for table tops, dressers, cupboards and other fitments of a house : also for Hoor boartls, as it will keep its clean appearance. The narre whitewood is also given to hass (q.v.).

WHITING : How to Cook. Small had docks are sometimes substituted for this fish, but they do not possess its delicate Havour. When unskimed, the haddock may be easily distinguished by its dark markings and the barbule on the chin. The whiting when skinned looks compact, and the head is small. Rock whiting is the best kind.

For frying, the whiting should be skimned after heing gutted; the head should be turned round and the tail thrust through the eyes so that a circle is formed. When trussed, dip each fish into seasoncd Hour. Then brush with beaten egg and cover with brcadcrumbs.

It is better to use a frying hasket when cooking whiting, as the shape will be preserved intact. Fry the fish, according to size, from 5 to 7 min., then drain and dish it on a folded fish napkin or paper. If three or four whiting are to be served, stand them up on the dish with the tails and heads uppermost, and gar nish with pieces of lemon and fried parsley Serve with shrimp or anchovy sauce.
To bake whiting, prepare three tish, skin and fillet them, making two tillets out of each
whiting. Dry the pieces well, and arrange them in a well-buttered baking or gratin dish. Season them with salt and cayenne, and add a little ground mace. Work together $\frac{1}{2} \mathrm{oz}$. butter with the same quantity of flour into a paste and distribute this over the fish. Then pour on to them $\frac{1}{2}$ a wineglassful port, the juice of $\frac{1}{2}$ a lemon, and $\frac{1}{2}$ a teaspoonful chilli vinegar. Cover them entirely with a thick buttered paper and bake them in a moderate oven for 15 min . When cooked, remove the paper and serve in the gratin dish. While the fish is baking. baste it once or twice.
Whiting can be fried, dipped in batter instead of egg and crumbs. Fillet three fish and place the pieces in a deep dish with three shallots pceled and chopped, a bouquet garni, seasoning, $\frac{1}{2}$ gill vinegar, and rather more of salad oil. Steep the fish in this mixture for 3 hours, turning it two or three times. Then drain the fillets, dip each in a fritter batter, and fry till a good golden brown colour. Garnish the dish with fried parsley and serve with parsley and butter sauce.

WHITLOW. The term whitlow is applied to intlammation of the fingers or toes, caused by the entrance of septic microbes. These may make their way into the tissues through scratches or puncturcs.
The septic poisoning may extend from the finger up the hand and forearm, along the lymphatic vessels to the lymphatic glands in the armpit. The infection may now extend into the blood vessels. giving rise to blood poisoning. In other cases there is a formation of pus or matter in the fingers. It should be let out at once, otherwise serious danger threatens the usefulness of the hand.
Rest in bcd, with a splint on the front of the forearm and reaching from the elbow to beyond the tips of the fingers, and poulticing, help to make the patient more comfortable.

WHITLOW GRASS. This is the name of a group of small early-flowering evergreen rock garden plants. They must be planted in gritty well-drained soil and a sunny place. The botanical name is draba. Draba aizoides, 3 in., which bears yellow flowers in April, is a favourite kind; others are bruniaefolia, 3 in., yellow; and pyrenaica, 3 in., lilac-rose : the last-named is usually grown in a mixture of stone chips and soil. These plants are best propagated by seeds sown in spring; they should be protected by raised pieces of glass in winter to throw off excessive rain.
WHOLEMEAL. Wholemeal differs from ordinary flour in that it retains the bran removed from flour in the course of milling. It is consequently darker and does not keep so well, but, on the other hand, it is more nourishing because the bran contains a large proportion of cellulose and salts.
Wholemeal bread is an ideal food for growing children, because it supplies them with certain indispensable organic phosphates. See Bread; Diet; Flour; Wheatmeal Biscuit.

## WHOOPING COUGH. Pertussis, or

 whooping cough, is an acute infectious disease, in which there is catarrh of the respiratory tract and a characteristic cough. This comes on in spasms of 10 to 20 short coughs, succeeded by a long, deep breath which is accompanied by a whooping sound, caused by spasm of the vocal cords.It is a dangerous disease when it occurs in infancy, or in older children who are debilitated from any cause. The disease is infectious from the beginning of signs of irritation of the bronchial tubes. The incubation period lasts usually about 10 days, and then the child may appear simply to have a bad cold.
The cough may assume its spasmodic form in from a few days to three weeks from the onset. During the cough the child's face may become blue and the eyes may bulge and become bloodshot. The cough may bring up
some thick mucus and often causes vomiting. If vomiting is very frequent, the child's nutrition will suffer. Someone should always be at hand to help the child during a paroxysm and to reassure it.
It often happens that a child suffering from measles develops whooping cough, and the converse is also true. The most serious complication is broncho-pneumonia.

Immediately a child who has not already suffered from whooping cough shows signs of catarrh of the nose and bronchial tubes, during an epidemic of the disease, it should be isolated. If confined in bed it is of the greatest importance that the sick room should be kept ventilated rlay and night. The doctor will advise upon the use of drugs and fumigations.

The patient should be fed with easily digested food, and if there is much tendency to vomit should have frequent meals of milk. When convalescing, malt and cod-liver oil will be bencficial, and a tonic may also be given. Children who have suffered from whooping cough are not supposed to go back to school till the end of five weeks at least, and only then if the characteristic cough has been gonc for two weeks. See Cough.

WHORTLEBERRY. This belongs to a group of dwarf shrubs, known botanically as vaccinium. Known also as bilberry and blaeberry, it bears blue berries valued for cooking purposes. The cowberry (Vaccinium vitisidaea), with red berries, is another British shrub. One of the best of the exotic kinds is the American blueberry (Vaccinium corymbosum), which grows 2 ft . high and bcars pale rose-coloured blooms in early summer. All need moist, peaty soil and slight shade, and can be propagated by cuttings or seeds.

WICKERWORK. This is another name for basketwork made with osiers, and is applied to baskets, stands, tables and chairs. Wickerwork repairs are often not worth troub ling about, owing to the limitations of the material. After being in usc for some time, the osiers become very dry and brittle, and if replaced with new material there is always a risk that the new stuff will prove too strong for the old portions left in. This is particularly noticeable when new lengths are woven between the old stakes.

If wicker chairs are danaged, the better plan is to effect repairs with a suitable thickness of pith cane rather than with osicr rods. The material can be rendered quite pliable by soaking it in water just before use, and it will dry out without straining the existing portions.

White wickerwork should be washed with a strong cold solution of salt and water then wiped as dry as possible and left in the sun to bleach. Hot water, which destroys the natural polish of the wood, should not be used; neither should soap nor soda, both of which have a detrimental effect. Brown wicker furniture is best cleaned by rubbing it with a rag dipped in paraffin. See Basket; Cane; Osier.

WIDGEON. The season for the widgeon is from early autumn till March. The birds should be selected by pressing the pinions; if these are pliable the flesh is tender. To prepare them for table, pluck, draw, and truss as for ducks, but do not stuff them.

To roast widgeon, brush the bird well over with butter and roast it in front of the fire, if possible basting frequently. A Dutch oven (q.v.) may be used with advantage. From 15 to 25 min . is considered sufficient to cook widgeon, as they are supposed to be of superior flavour if underdone. When ready, score the breast lightly and sprinkle over it lemon-juice and seasoning. Serve very hot with a made gravy, and garnish with watercress. The gravy should he rich, and flavoured with port wine and red currant jelly. When carving, remove the whole of each side of the breast. in the slice. See Game.

WIFE : Legal Position. As against her husband, a wife has a right to be maintained according to the husband's rank and means, and for this purpose, unless the husband is making her an adequate allowance, she may pledge his credit for necessaries. The word necessaries in this connexion is interpreted very widely.
What is neccssary for one wife would be a mere luxury for another. For instance, the wife of an earl would be entitled to order evening dresses at an expensive dressmaker's but not so the wife of a small tradesman or agricultural labourer. If a husband and wife are living apart, the wife, unless she has an adequate allowance, can support herself in this way so long as she can find tradespeople who will supply her with goods on her husband's credit. She forfeits this right, however, if she commits misconduct.

With regard to the guardianship and custody of children, when a husband and wife are living together the husband is the guardian, and if they separate he has a prima facie right to the custody of the infants; but this right is more nominal than real, because on the application of the wife the court will, unless she is an unfit person. invariably order that she have the custody of very young children and all girls of any age. At the same time the husband remains, in law, the guardian of the children.
A wife cannot compel her husband, whether living with her or not, to grant her an allowance, nor has she on her husband's death any right to any part of his property unless he dies intestate. By the law of England her husband can make a will and leave all his property away from his wife. If he dies intestate, whether there are children or not she has the right to take all the personal chattels, i.e. the household furniture and effects, including such things as motor cars which are not used for business, and the sum of $£ 1,000$ free of all death duties and costs. If there is no issue, she also takes a life interest in the rest of his estate ; and if there is issue, then a life interest in half of the estate. A husband possesses a similar right in the property of his deceased wife. See Child; Divorce ; Guardian ; Husband; Marriage.

WILD DUCK. Probably the best way to choose a wild duck is to examine the feet and press the pinions. The feet should be supple and the legs limber, and the pinions when pressed should not be rigid. These birds are in scason from August to February. The only objection is a slight fishy taste, which is easily removed if the bird is put into the oven in a tin of salted water and cooked for 10 min . The tin should be covered. After this the duck is trussed and roasted in the same manner as tame duck. See Duck.

WILD GARDEN. Many gardens of fair size have a portion where aspect, soil, and other conditions are not favourable for the choicer plants. Such positions will accommodate a host of shrubs and plants of somewhat grosser habit at small cost and with comparatively little labour. However rough the spot may be, there is opportunity for planting bulbs, perennials, and shrubs, and, as bold grouping is of the essence of this form of natural gardening, it follows that the greater the space that is available the more effective will be the result.

Spring-flowering bulbs may be naturalized among the trees and shrubs, and some of the lilies are suitable for planting in partiallyshaded places. where also the Japanese primrose and the common primrose still flourish. Some of the shrub roses are splendid plants for the wild garden, especially the musk roses named Felicia, Penelope, Prosperity and Pax; Rosa Moyesii, which bears rose-red single flowers and large red hips, and the

Japanese briar (Rosa rugosa), valued both for its flowers and fruits. Other shrubs suitable for planting in the wild garden are Berberis Darwinii, Berberis stenophylla, mock orange, Spanish broom (Genista hispanica), the common broom (Spartium junceum), double gorse, the common Rhododendron ponticum, heather, Mahonia (Berberis aquifolium) and the pheasant berry (Leycesteria). See, Rock Garden ; Water Garden, etc.

WILL : How to Make. A will is a declara tion of the person making it with regard to matters which he wishes to take effect upon, or immediately after, his death. It need not necessarily be a disposition of property. be cause a man may make a will merely to appoint guardians of his children, or to appoint an executor. But as a rule a will is a document by which the person making it, who is called the testator. disposes of his property after his death

In England anybody of the age of 21 years and upward may make a will, and by it he may dispose of any property he has, or to which he is entitled, or over which he has a power of appointment. Except as to the wills of soldiers on actual military service or mariners actually at sea, every will must be in writing and signed by or on behalf of the testator. Such signature must be either made or acknowledged in the presence of two witnesses who are both present at the same time and both affix their signatures in each other's presence as well as in the presence of the testator. A will may be written on anything which is capable of receiving writing and either in pencil, ink, chalk, or any othes substance that can make a mark. A testator who cannot write may make his mark, which will be accepted if it is duly witnessed
Valid and Invalid Wills. It is essential to the validity of a will that the testator should act voluntarily, i.e. of his own free will, and be of sound disposing mind, which means that he must know he is making a will and know what the effect of the will is. For this reason a lunatic cannot make a will unless in a lucid interval. Further, if it be proved that a will was made under undue pressure, eithe physical or mental, the court will upset it. At the same time there is nothing to prevent. for instance, a wife requesting her husband to make proper provision for her or her children in his will.

The kind of case where a will is upset owing to undue influence is where some person very old or feeble in mind or body is more or less compelled by someone who has great influence over him to make a will in that person's favour, or to give favour to someone through whom that person derives some benefit. A will induced by fraud will also be avoided, e.g. where a man made a will in favour of $\mathrm{X}, \mathrm{X}$ having fraudulently told him that his, the testator's, only son, who was on a voyage, had been drowned.

Until 1926 a will was revoked by the marriage of the testator, but now a will which is made in contemplation of marriage is not avoided by that marriage taking place. A young man about to marry, and wishing to make a will to provide for his future wife before the ceremony, should begin somewhat in this form: This is the last will of me, John Jones, of 490, High Street, Peckham Whereas I have arranged to marry Annie Robinson, now I make this will in contem plation of such marriage. He should then go on to dispose of his property according to his wishes and responsibilities.

A gift by will which is illegal, or against public policy or morality, is not good, e.g. where a man left a fortune to his son on condi tion that the son separated from his wife or a gift for some superstitious purpose, as where someone left money for the education of spiritualistic mediums. Everyone who
makes a will should take great care to begin by appointing an executor, or even more than one, because if no executor is appointed a great deal of extra trouble and expense is incurred in proving the will.

A will is, by the law of England, always revocable, even though it is expressed to be irrevocable. It can always be revoked by a later will or codicil which purposes to revoke the former, and, indeed, most wills begin with the words, "I revoke all former wills and testamentary dispositions by me made." It can also be revoked by cancellation or destruc tion ; but the mere destruction of a will, if it is done without the intention of revoking it does not revoke it, and it can be proved by evidence, such as a solicitor's draft or even a verbal recollection of anyone who has seen it as was done in the famous case of the will of Lord St. Leonards. In the same way. if the testator tears up his will when he is insane or drunk, it is no revocation. As a will can only be revoked by the testator himself, it follows that he cannot delegate to somebody else the power of revoking after his death.

Alterations in Wills. If it is desired to make an alteration in some of the dispositions of a will already made, it is not necessary to make an entirely fresh will. The testator can execute what is called a codicil, which ought to begin with the words: This is a codicil to my will dated the $X$ day of $X$. He can then, for instance, revoke a particular legacy or appoint a fresh executor or give an addi tional gift

If he intends to make an additional gift to someone who already benefits, he should be careful to make it quite clear that it is addi tional. Thus, if he has left $£ 500$ to his son John and wishes to increase it to $£ 1,000$, be should say: Instead of the $£ 500$ given to my son John, I bequeath the sum of $£ 1,000$. Or he should say: In addition to the $£ 500$ bequeathed by my will I give him another £500. If he simply says: I give my son John $£ 1,000$, the question will arise whether be means John to have the original $£ 500$ and the $£ 1,000$ as well. Clearness is the very essence of making a will, and technical terms are not at all necessary.
The ordinary family man who makes a will to divide his property amongst his children will generally find it best to divide it in proportion rather than in sums of money, because sometimes investments diminish or increase in value, and although the testator may think that his invest ments are worth $£ 5,000$, and that he is safe in saying that he gives $£ 1,000$ to each of his sons, it may turn out that the investments cannot be sold for more than $£ 4,000$, and very often complications arise.

If a testator intends that a business which he has shall be carried on for the benefit of his wife or family he should make it very clear that his trustees are to have that power. He should also make it quite clear if be intends his money to remain in any particular kind of investment, e.g colliery shares, otherwise the executors and trustees will be bound to convert all the shares into money and invest it in trustee funds.

Scots Law. As in other matters the law of Scotland on the subject of wills differs in some respects from that of England. Mutual wills, or wills made by two persons jointly, are per missible in Scotland although not in England More important is the provision of Scots law by which a will is valid, although it is not witnessed, provided the testator hay written it wholly in his own hand. See Administration Executor: Estate l)uty; Intestacy ; Legacy

WILLIAM AND MARY STYLE. It has been said that the decorative arts in the reign of William and Mary reached a gorgeous ness and beauty that has ncver been surpassed The style was the culmination of the baroque period in English decoration, marked by a development of the lavish ornament in fashion during the later Stuart times, and also of the Dutch influence, which had already been seen in the furniture of the reign of Charles II, made after 1670, when a number of Dutch craftsmen, particularly cabinet makers. were employed in England by rich patrons

Architectural changes also showed Dutch design or inspiration. In some of the earlier houses built in the reign of William III the characteristic feature of the scrolled outlines to the gables at each end of the roof is found, while towards the close of the reign and during that of Queen Anne, Dutch architects had considerable influence on English house planning.

Reception rooms in the great houses were spacious and magnificent. Wall panels were large, with richly carved mouldings surmounted by applied swags of flowers, fruit and foliage. after the manner of the Grinling Gibbons carvings. Pilasters Hanking doors. windows and chimney pieces, also pediments to these, and the ceiling cornices were decorated with carving. Oak. walnut and pine were used for panelling, the last wood being sometimes painted green and the carved enrichments gilded. Cedar, pear and lime werc the woods chiefly employed for the applied carvings on oak or walnut. Fireplaces were smaller than in the Jacobean period and usually had marble rectangular surrounds. The hearths were provided with large fire dogs, as logs were stil! the fuel employed.

Floors were of parquet, often inlaid and partially covered with small carpets. These were usually imported, but at the Wilton factory English carpets had begun to be woven. Lighting fittings included central chandeliers of metal or painted wood and candle sconces with reflectors of bright metal or mirror glass.

Characteristic Furniture Chinese lacquer was fashionable at this period, beautiful cabincts being mounted on gilt or silvered stands after the style of the somewhat carlier piece illustrated in Fig. 1 of the article on Lacquer Work. Lacquer cabinets were imported from Japan. done in the Chincse manner, and though the finest examples were not allowed to be exported from the Imperial factory in Japan, some good pieces were made there for the foreign market. The carved wooden stands were made in England, later pieces of the 17 th century showing
the ornate stretcher work which is sucb a Oyster veneering is typich of this style, and feature of the William and Mary style. A so is the finest arabesque marquetry. See heautiful writing table in black and gold Jacobean Style Marquetry: Oyster Grain Incquer is illustrated in Fig. 2. The Hat, shaped atretcher is most characteristic. as also are the heavy bun feet.
Dutch influence is noted in the furniture by the more extensive use of upholatery and cortly textiles, and by the introduction of the cabriole leg. although this latter was not the typical furniture leg of the earlier pieces of this period, a good example of which is here illustrated on the chair of beautifully carved walnut. This chair is 4 ft .3 in . high and is upholstered in groen figured velvet Twisted spiral, baluster and spindle logs are also found

Queen Annc Style
WILLOW. This is one of the hest trees for planting in damp or even wet land; the weeping willow (Salix babylonica) is a most beautiful watcrside tree. The blue willow (Salix caerulea) provides the wood from which cricket bats are made. Several of the willows have coloured bark which is most ornamental in winter: the best of these are vitellina, which has yellow, nnd cardinalis, which has red hark; these must bo hard pruned each spring. Willows are largely grown for the purpose of basket making, and one kind, Salix frngilis, is used in the manulacture of riddles or sieves. Salix alba is one of the hest willows for general planting. The catkins of two British willows (Salix caprea and cinerea) provide the popular "palm" in spring. Willows arc easily propagated by cuttings 12 inches long inserted out of doors in autunin.

Uses of the Wood. Willow is a soft, light woorl with smooth, lustrous surface, tough and pliable, brownish or yellowish white in colour; it may he bruised by a blow but is not likely to split. Its most important use is for cricket hats,
William and Mary. Fir. . . Writing table in black and
on the earlier chairs, tables and stands. In some of the chairs the barks were entirely upholstered, while in others the framing was exposed. Some had cane panels. Beech or walnut was used for frames, the former being often painted or gilded. Fringe and galons were employed to trim both chair and settee covfrings of damask hrocade, velvet and needlework.
The cabriole leg seen at the end of this period was pronounced in curve. and usually terminated in a heavy bun foot. The idea of these feet originated in the blocks of wood placed by Dutch housewives to save the legs of their furniture from being rotted by the constant damp arising from well-washed tiled flonrs.

Cabriole legs were united by hooped or curved stretchers, often with a turned finish in the centre. This system of under-framing chairs replaced the carved deep rail below the seat directly connecting the two front legs, with simple turned rails running at the sides and back Completely upholstered settees had high arched hacks and six or eight legs braced by crossed serpentine stretchers.

During the later period of the style carving gave way to marquetry for the decoration of cabinets, secretaires, table tops and chests of drawers. Such ornamentation was helped by the arrival of fine woods from the Dutch Indies. Entire surfaces were covered with thin veneer, the pattern and background being fretted out by cutting through two or more sheets of wood at a time and interchanging pattern and background. The carcasses were of pinewood. In cases where the geometrical design was relieved by floral work the motif is frequantly seen to be the jasmine, treated conventionally, a form of decoration which dates a piece fairly accurately as belonging to this period.
but only the hest parts of the tree are
er About 170 good nough for this instead of sawn. Willow as tlooring wears well and has a smooth surface susceptible of a fine polish. hesides being non inflammable. It is employed for hurdles, poles, cutting boards, knife boards, and by the cooper and turner; scrap willow is used in toymaking. Sometimes spade and shovel handles are of willow, and next to alder it is the best wood for clogs.

The chief varieties are known as white and red willow; the latter, which has a red tinge is generally preferred, but it is not plentiful The willow is much cultivated for wickerwork and basket making and is not allowed to grow beyond the stage of osier or withy rods With this are used the twigs and small branches which are cut periodically from growing pollnrd willows. Another way in which young willow is used is by splitting it into thin slices for making woven crates, hampers. haskats, and hats. See Osier; Wood.

WILLOW HERB. The common name of a group of hardy plants, of which the most familiar is the rose bay (Epilobium angustifolium), which grows wild in many parts of this country: it reaches a height of 4 feet and bears rose-purple flowers in early summer.

WILLOW PATTERN. Hased on severa! Chinese originals, the willow pattern was evolved by Thomas Minton, the engraver, for use on china dinner ware. In the earliest version, dater 1780 , there were only two figures on the bridge, no flying doves, and no cedar trees bearing the so-called apples. It was introduced at Caughley by Thomas Turner, who printed it uncler the glaze, gencrally with a blue crescent mark, and also with $C$ nnd $S$ or even the crossed swords device.
The engraver and his assistants supplied copper-plates of the pattern to other works.
after varying the details and introducing the doves and the fruit. Josiah Spode, who printed his willow pattern by transfer in 1784 , had a design with a pagoda on the left and a buttertly border. and another with $n$ dagge horder The willow pattern sprang into favour from the first and was applied to a wide rangc of wares. Davenport plates have 25 apples, with a special fret pattern round the rise. Spode has 32 and Wedgwood 34, while Adams plates have 32 and the dishes 50. Both Spode and Wedgwood did the Caughley pattern as well as their own. Differences are ohservable in the depth of the blue tint in the printing the Adams cobalt being especially sought after. During the early 19th century the pattern was produced on various bodies, often marked with the Staffordshire knot, and not always in blue. It remains one of the standard designs of the modern potter and is still made by Mintons and other historic factorics in the traditional form. See China : Davenport Ware: Pottery; Spode etc.

WINCEY. This fabric is a wool and cotton mixture. It is obtainable in white, some colours and stripes, and is especially suitable for children's light-weight pyjamas The little wool that it contains makes it warmer than cotton of equal substance and less perilous than fannelette.
WINCH. The use of a winch is for winding up rope, etc. on a revolving drum in various kinds of apparatus used in hauling. It comprises a crank with a handle and geared by means of coggcd wheels to a drum A winch is commonly seen in the apparatus used to draw water from a well: it is used for winding the rope on a crane and is generally provided with a pawl to prevent unwinding.
Wind : In the Body. See Flatulence.
Windflower. This name is given to plants of the genus anemone (q. $\mathrm{\nabla}$.).
WINDOW. The form of a window dipends chiefly upon its position in the building and the room which it is to light. Its proportion necessarily varies, and the type will be chosen to suit the design of the building.

The various types of window include the bay. which may be square, angular, or curved, the cascment, plain and transomed in hoth metal and wood, the dormer, the French, also made in metal and wood, the gable, the jut, the mullion, and the oriel. The sash window is more commonly fitted than any other, but in modern construction it is being superseded by the more convenient casement. The mullioned window with transoms. the hay with latticed casements and the oriel in a simple form are all adapted to Tudor styles in huilding.

Typical examples of most of the above types have been fully described and illustrated in this Encyclopedia under their respective

Willow Pattern. Plate decorated with this quaint pattern derived from Cbina and now a standard English design
headings. (See Glass and Glazing: leaded Lights; Stained Glass.)

An inexpensive glass is obtainable through local glaziers or builders which transmits the vital ultra-riolet rays shut out by ordinary window glass. Many people have this glass fitted to the windows of nursery and living rooms It is made up in clear sheet, plate and catherlral forms for sash windows or leaded lights. This glass is belpful in counteracting the ill effects of a badly lighted hasement flat.

Vindows may be recessed, Hush, or may project : in all cases they should fit into a rebate in the wall, which may be formed by a depression in the brickwork or by an iron har fixed into the mortar joints. For recessed windows the rebate is in the interior side of the wall and in Hush windows on the outside.

All wood windlow frames should he kept in good condition by applying periodical coats o: paint to make them weatherproof. Certain forms of metal frame are provided with small grooves or troughs in which the rainwater is caught, and this prevents it from collecting at the liottom of the window.

Properly constructed windows should not rattle If the meeting railo are made such a width that the sash fastencr. on pulling them tightly together, also pulls them tightly to the parting beads the window sashes will not rattle If, however. when the meeting rails are close together, there is a space of $\frac{1}{2}$ in. between the stile of the top sash and the line of the stile of the bottom snsliand the parting bead is cnly ${ }^{3} \mathrm{in}$. thick, the window will shake considerably in the slightest wind On the other hand, if the stiles of the saslics are within in of each other, the fastener will pull all tight togethor, and so, no matter how high the wind, tile windows will be silent.

Window Cleaning. In most towns there are window clesners who will do the windows of the whole house at a modernte charge, and who are usually called in, at any rate, for the less accessible ones. Those that can be done by the ordinary domestic ataff sliould be cleaned on a dull day, or at least when the sun is off the window: they should not be cleaned in cold or frosty "eather. The materials required are a pail of clean warm water with a little paraftin in it. a wash-leather or cloth for applying the water to the window : a soft cloth, preferably linen, for drying, and a dry selvet, soft duster, or wash-leather for polishing Before starting, the frames should be brushed.

The water should be sluiced over lightily, so as not to scratch the panes with any dirt that has adhered to them, but care should be taken that all dirt is removed before they are wiped over with the drying cloth. When all the wet has been dried off with clean, swecping movements. the panes may be polished with the polishing clath, and any smears loft by the damp cloth removed. A little methy!ated apirit on the cloth will ensure a fine polish, but the paraffin in the washing water is also excellent for this purpose, and it keeps flies a way When no suitable cloth or selvet is available for polishing, a piece of clean newspaper rolled up into a loose pad will be found to make an excellent substitute. Sec Bay Window; Blinds Burglar Alarm; Casement; Curtain: Fiench Window; Glass; House; Lead Art Craft: Pelmet : Sash; Transom, etc

WINDOW BOX. Plants may be grown upon the window-sills of flats, town houses and other buildings by the use of window boxes Such a box may be made of wood, about I in. thick; it should be the length of the sill upon which it is to stand, and ahout 1 in . vider A dejpth of 9 in . is suficient.

Ridges or runners of wood should be placed at each end in order that the box may not rest directly upon the sill A few holes should be bored in the bottom and shallow tins or trays such as the lids of discarded biscuit boxcs may be slid under the bottoms of the
boxes to catch any superiluous moisture. Before being placed in position, window boxes should be hurned or charred inside so as to present a resisting surface to the decaying qualities of moisture

A simple form of window box is made with 9 in. by 3 in boards cut out to the size of the sill and nalled together, with due allowance for the slope of the sill. The latter aljustment can he made by inaking the front board wider than the back one, or by fitting wedges under. neath. If flower pots only are placed in the hox there will be no need to do more than bore a few holes for drainage, but if the box is filled with soil the inside can be lined with sheet zinc Metal flower boxes can be hought which are inexpensive and requirs no lining, but such boxesare ugly unless it is intended completely o cover their outer sides with 1 railing creepers.

Preparation and Planting. In preparing the box to receive plants, the botton is first filled to a depth of about I in. witl broken brick, crock, or ot her material in order to form a drainage. On this is placed a layer of turf or rough soil and the remaining space is filled with n compost of loam leaf-mould and sand

In the spring nasturtiums may be planted to droop over the front of the box. or creeping jenny. or canary creeper. Behind theso, ycllow or brown calceolarias, white daisies, or heliotrope Lard Roberts may be planted. Combinations of colour must be care fully thought out White, yellow and bronze or mauve look well together, while pink geraniums will be charming with either lobelia, catmint or mauve violas in front. Begonia Lloydi is most attractive, as it droops over the front of the box and has double flowers in yellow. scarlet or pink:

When the summer flowering subjects are over, the boxes should be cleaned out and refilled for the winter display, consisting of plain and variegated cuonymus and other small evergreens.

WINDOW SEAT. A window seat generally lakes the form of a Hat bonrl fitted to the shape of the window recess, supported on a suitable framework: and fitted with cushions or upholstered.

In a simple form of construction the seat board, measuring from 15 in . to 18 in . wide, is

With the aid of plugs at a height of about 16 in . The lillets should be at least 1 in . thick, and chamfered on the front and lower edges. If the recoss is a long one. one or two bracket sup. ports will be required for the seat, and in making them due allowance must be made for the skirting hoard as shown in Fig. l. Having fitted the end fillets, as at, A. from? 2 in . by 1 in. wood. a length of similar wood B, which can be obtained machine planell, should be fitted between and secured to the wall, great carc being taken that the back strip is exactly equal in thickness to the skirting : otherwise it, will have a faulty appearance.

The brackele as shown in side elevation in Fig. 2 should be framerl up from 2 in by 1 in . wood on a back picce C, which should be the same height as the top of the fillets. The horizontal piece 1) forming the top of the bracket is dovetailed to the top of the back piece, as in the plan in Fig. 3 : it should he cut

Fig. 5. In the old-world hall of a converted tarmbouse a suitade window seat has been constructed with panelled back and solid shaped brackets

Ilumphren \& Vera Joel
to a length that will bring the end 1 in. from the front edge of the scat board. The strut is fitted as at $\overline{\mathrm{E}}$. The brackets are screwred to the back fillet, as in Fig. 1.

If it is not clesired to make the seat a fixture, a light framework as in lrig. 4 can support the seat hoard, the wood used being at least 2 in . by 1 in. : corners and rail can be jointed with the lapped halving joint or the frame mortised and tenoned. For long seats it is better to use $1 \frac{1}{2} \mathrm{in}$. square materia!, the joints being mortised and tenoned. To prevent the supports from moving, one or two rails are tenoned into them and further secured by pinning or fox wedging. The top hoard in all cases should be 1 in. thick, and as the width of the seat will be greater than the average width of the muterial, two lengths must be glued together. Information on srats of a similar type will he found in the articles in this work on Corner Seat and Ingle Nook.

A winciow seat inten-

Window Seat. Fip. 1. Recess ready for seat board. Fig. 2. Bracket. Fig. 3. Plan of bracket.
wax polished and having a simple panelled bark and solid shaped brackets, as shown in lig. 5. Any form of upholstery would be out of place in such a setting, though one or two flat velvet cushions, edged with cord and trimmed with heary tassels, would be permissible.

For a more up-to-date style the most convenient covering for a window seat is a fitted cushion like the one illustrated in Fig. 6. Velvet has been selected as the fabric for the cushion in this case to match the upholstered

Window seat. Fig. 6. The most convenient way of furnishing a wo fancy cushions to suit the general colour scheme
of the ordinary Windsor chair were niade of beech or birch. The seat was made of elm, which was cut up into rough planke. An adze was used for the hollowing process and the scat made smooth with a spokeshave. Each p!ank was then cut up into the required number of chair seats and cach seat shaped with a band saw. A bit bored the holes that received the rungs. The picces were allowed to dry before they were put together with glue.
These chairs were also made of yew, walnut, and cherry wood. Yew ones are very valuable as age gives the wood a heautifu! tortoisealiell colour and a finc patina.

## See Chair.

WINE. All wines possess a peculiar aroma or perfume which constitutes onc of their most valued propertics. The way to tell good wine is by its appearancc, its smell, and its taste. Re the wine young or old, it should be clear and brilliant in colour, not dull or thick. It should be clean-smelling and of a pleasant aroma. Its taste should also be clean and pleasant.
Wines are often classified into natural and made or manufactured and fortified wines, but these class:fications are not absolute. The white and still wincs of France, Germany and Italy are matured gencrally according to natural processes, and untouched thercafter. Made wincs arc all sparkling wines, such as champagnes,
chnirs, but tapestry, damask, printcd liuens, cretonne or clintz would all be equally suitable in correct relation to the curtains and chairs of the particular room. See Bay Window.

WINDSOR CHAIR. This type of chair, a real English production, was first made in the 17th century, and good examples are much valued. The characteristic features are the hollowed wooden seat and the complete separation between the uprights forming the back and those forming the legs. The method of putting it together also was new. This was the boring of circular holes by means of a bit, and the fitting in of cylindrical spars, fastened by wedges and glue.
In the oldest form, the backs are composed of simple turned spindles, or spars, that run into a curved top rail. The arms are continuations of the back centre rail. Another type has a stretcher hack in the form of a V . This is fixed by two extra spindles fitted in the back for additional strength. These are put in behind the others, which they cross trans. versely, and are fixed in a tailpiece to the seat.
The fiddle splat back type was seen early in the 18th century, the splat probably having been copied from that in the ordinary Queen Anne chair. In thesc cahriole front legs are often seen and they possess stretchers. About 1750 the Windsor chair with an arch back was made. In this the cabriole leg is used, and the front stretcher is curved away towards the back legs, being connected therewith by two turned stretchers. The back is in the form of an arch and is usually supported by six spars with a centre splat laid on, which may or may not be pierced. The arnss are often horseshoc in shape.
A variation of the splat in the arch back is the wheel back. The centre has a circular pierced ornament in the form of a wheel made by fretting out six triangular holes. The legs
which have added a liqueur composed of fine wine-brandy and sugar.
Port and sherry are very often fortified by an addition of alcohol, but the finest vintage port is a natural wine free from added alcohol, thereby enabling the wine to keep and rendering it wholesome. Well-made winc improves with age. Port or sherry will last for 80 or 90 years or more, a good burgundy or claret for 40 or even 50 years. Channpagne is at its best at from 12 to 15 years after bottling.
The Wine Cellar. Every lover of wine should keep a wine cellar. It need not be an elaborate affair. A good-sized cupboard will do provided it is dry, or any underground cellar that has not outside walls. The temperature should be from $53^{\circ}$ to $58^{\circ} \mathrm{F}$., and this can be obtained by means of a gas jet. The great thing is to keep the temperature uniform.

Bins made of iron and wood in two.dozen units for holding the bottles car be obtained inexpensively at any ironnonger's. The bottles should be placed in the bin on their sides and, once binned, should be left undisturbed until required. On port bottles is a splash mark, and the bottles should be binned with this mark uppermost. Sparkling wines soon become flat if they are stood on end.
The Decanting of Wine. Great care should be taken in decanting old wines, especially old vintage wines. First of all the sealing wax should be

Wine Cooler. Antique silver wine cooler having a lid with a knob formed of vine leaves. Period of George III
sod to carefully. Then a brush should b A good corberew is or cork corks a double-liner extractor is nseful. When drawing a cork, a guard should always be used consisting of a piece of cloth or a leather guard which is slipped over the neck of the bottle. In the case of old wines, it is wise to decant through a decanting funnel or a piece of muslin. If a funnel is used, it should be warmed to the temperature of the wine.

When opening champagne, the wire and string should be entirely removed before un corking. The wine may be spoilt easily if poured out over string and rusty wire. Do not put more than one bottle of wine into a decanter. Each bottle of wine has its own eharacter and individuality. Do not decant more wine than you think will be consumed.
Temperature for Serving. As for the temperature, white wines should be a few degrees colder than the room, and in hot weather fullhodied wines may cven be iced. Red wines, on the other hand, should have had time to take the temperature of the room, a matter of two or three hours, and there is no objection to their being a degree or two above it. But it must be remembered that if wine is at too high a temperature all its finer qualities will disappear, and the particles which it gives off will be so loaded with alcohol that perfume, bouquet, and aroma will become indistinguishable. The wine glass should be as thin as possible so that the wine may be affected by the heat of the hand without delay, and it should be of a bulging shape, with its opening smaller than its body, so that the perfumed particles given off by the wine may be inhaled, as it were, concentrated through a funnel.

At amall, informal dinner parties it is now usually the practice to serve only one or two wincs throughout, claret, burgundy, or champagne. But at big dinner parties and banquets there is a recognized order, as follows: With oysters, graves or chablis ; with soup, sherry, marsala, or madeira : with fish, a glass of sauterne or chablis; with the entrée and roast, claret or burgundy ; with game, champagne: with pastry, madeira ; with checse and fruit, port should be served. See Burgundy; Champagne; Dinner ; Port Wine; Sherry, etc.

WINE BISCUIT. To make, sift 8 oz. fine flour with a pinch of salt, then rub in 2 oz. butter, add the same amount of castor sugar, and make all up into a dough with 1 small egg and about 1 tablespoonful cream. Add to the dough, mixing in lightly 2 oz . currants cleaned and picked or $\frac{1}{2} \mathrm{oz}$. caraway seeds. Lay aside for 1 hour to stiffen the dough. Cut it into shape with a fluted cutter and bake it on a greased and floured baking tin in a moderate oven.
WINE COOLER. This article, now mainly valued as an antique, developed from the tub or vat in which bottles of wine were placed for cooling. It was also known as the ice pail. These coolers or pails are often found in pairs, and the fact that their usual place was bencath the centre of the sideboard was not without influence on the design of that piece of furniture.
Silver bowls were used for cooling wine in Italy in the 16th century and something of the kind was used in England in the 17th, but the best examples, both in silver and in Sheffield plate, date from the 18th. Pien.es were made in the
shape of an urn or vasc, and some of them are corrections to be made in doubtful blendings of remarkably graceful in design. Some are provided with a lid and others with a handle or both lid and handles, but there are examples without either.

In some cases ring handles have lion mask supports and lie llat to the sides; in others, as in the one here illustrated, the handles are high and ornanented with twisted snalics or with vine branches. Bases were square, round or oval, and some of the earlier examples were on scrolled feet.

Probably the finest existing examples are those copied from the Warwick vasc. One beautiful specimen stands on a square base and is lecorated with bead elging and acanthus leaves on the body and a band of leaves round the top and along the sides of the basc. See Sheffield Plate ; Sidehoard.

WINE GLASS. Convention has decrecd that each wine shall have its particular pattern of glass. Claret glasses should have the sides sloping slightly outward and should hold about a third of a pint. For burgundy the glass should be slightly bevel shaped on a short stem; it should hold nearly half a pint.

Certain white wines, such as cliablis and sauterne, should be drunk from glasses of the ordinary goblet shape with straight sicles. The champagne glass had a very wide, shallow bowl, the idea being that this keeps the wine fresh by retaining its effervescence; modern champagne glasses are often unconventional in shupe, the same type being used for hock or moselle. These glasses arc sometinies gilded at the rims, decorated with black or coloured stems, or made in delicatc colours with cut stems. Sherry glasses arc tall and pyramidal in shape, and port is usually drunk from a somewhat smaller glass shaped like a cup. Sec Glass Ware.

WINKLE. The winkle or periwinkle is a small sbellfish which has little food valuc. The horny excrescence which surmounts the head should always be removed. Winkles are usually caten with vinegar and scasoning and accompanied by bread and butter. See Shellfish.

WINTER: In the Garden. Winter is chietly a period for repairing past crors and planning new schemes in the garden. Dead stems, leaves, and all sorts of rubbish may be cleared away and burned, but it is always desirable to establish the identity of each plant before removing the top hamper, otherwise the label may be lost, or illegible, and doubt may arise in the futurc.

Roses and fruit trees may be planted when the weather is open, and other operations carried out according to the calendar for the rarious months of the season.

Quite a number of slirubs and plants are in full bcauty during the winter months. The yellow winter jasmine is charming on a house wall or fence, and the pink buds and white flowors of the evergreen laurustinus arc cheerful. The Chinese witch hazel (Hamamelis mollis) bears fragrant ycllow blooms in midwinter and the heather named Erica darleyensis is also in flower. The spring heather (Erica carnea) shows colour carly in the new year, and on n sunny wall the old red Pyrus japonica and the fragrant winter swect (calycanthus) then begin to llower. The earliest and best of the Christmas roses (Helleborus altifolius), the winter-llowering Iris stylosa, stray blooms from the winter-llowering pansies and poppy ancmones, snowdrop and winter aconite-all these help to invest the garden with intercst in the depth of winter. Then also the trees and shrubs grown for the sake of their coloured bark or showy fruits are in full heauty.

Systematic gardeners will propare and map out on paper new plans for heds and borders to be established in the spring, or not
corrections to be made in doubtful blendings of
heights or colours. See Autumin ; December ; January; Spring.
WINTER ACONITE. This is a charming low-growing, spring-flowering bulb, the first to open in the new year. The yellow blooms surrounded ly a ruff of green are on stallis about 2 in. high. It looks well in grass, or may be set among shrubs where it will spread and provide a carpet of colour early in the ycar. The bulbs should be set 2 or 3 in . deep in August and September The botanical name of the common kind of winter aconite is Eranthis hyemalis.

WINTER CHERRY. A
hardy herhaccous plant, known also as Chinese lantern, the winter charry is prized for its large orange yellow "fruits" which are so popular for room decoration in sutumn and winter. These "fruits" are really enlarged calyces. The two best linds arc Physalis Franchetti and Bunyardii; they grow 2 ft. or morc high, may be planted in autumn or spring, and thrive in ordinary well-drained soil. Propagation is by division in autumn. See Solanum.

WINTER GARDEN. In the ordinary acceptance of the torm this is simply an claborate and large conservatory attached to a house, with sufficient space for indoor beds and borders, and roof-roon of an altitude that will accommodate the loftiest palms. The winter garden is usually heated by hot water pipes, and is often utilized as an after-dinner lounge. An outdoor winter garden suitably arranged would include such flowering shrulis as winter swect, winter-floweling jasmine, heaths, dogwood, hamamelis, laurustinus and the carliest bulbs, See Conservatory; Dogwood; Lounge.
WINTER GREEN : The Plant. Two useful evergreen slirubs are known by the name of winter green-Gaultheria shallon and green procumbicns. The former grows 2 to 3 ft . high, bears blush-coloured flowers in spring and purplish-black fruits in nutumn; it is often planted as an undergrowth beneath trecs. The partridge berry (Gaultheria procumbens) is a crecping shrub suitable for planting in shade; it has white Howers and red berrics; the latter provide the winter green oil used in the treatment of rhcumatism. Propagation is by sceds and cuttings.

Oil of winter green consists mainly of methyl salicylate, and has the same effects on rheumatism as other salicylates. It is chiefly used as an external application.

WINTER GREENS. In the vegetable garden it is very important to provide for winter use a supply of grecnstuff or winter greens, such as cabbages, Brussels sprouts, broccoli, kale, savoys, and sprouting broccoli. To avoid any glat, sowings sliould be made in small lots in March and April. A fresh sowing can be made "hen plants sown previously are just showing through the soil, thus providing plants which will mature in succession instead of all coming 10 harvest at one time. As a rule amateurs will not sow in this way, and consequently huge quantities of green vegetables either rot or run to seed cvery winter. See Brussels Sprouts; Kitchen Garden, etc.

WINTER JASMINE. This charming hardy winter-flowering, climbing shrub of slender growth is suitable for training on a house wall, fence or trellis. It flourishes in ordinary soil, and should be pruned as soon as the flowers lave faded. The flowers of the winter jasmine are ycllow and open we! in water, if spravs hearing buds are cut and brought indoors. See Jasmine.

WINTER MOTH. One of the worst pests of fruit trces is the winter moth, its caterpillars devouring leaves and blossom. Grease banding in antumn is necessary to trap the wingless females, which crawl up the stems of trees to deposit their eggs in crevices of branches and shoots, these hatching out into destructive !arvae as buds begin to burst. In addition to grase-handing, trees may be sprayed with a tar-oil wash in winter, and the poisonous arsenate of lead wash as soon as the fruits are sct. See Grease: Spraying.

WIRE : Its Uses. Wire can be obtained in many different shapes and sizes, and is machined commercially when means of powerful through a series of holes of gradually diminish. ing si\%e in a metal plate. Wire is employed for innumerable purposes in the home. It can be used for binding and repairing, for clothes lines, for supports for Howers in the garden or in pots and for hanging pictures and curtains. It can be kept straight. for the latter purpose by usitg wire strainers, and it is niso obtainable in coiled spiral form for the same purpose. It is made up in the form of nails, pins, hooks, staples, and tacks. Wire is found in the form of gauze, netting, fencing and is also made up ¡nto many houschold utensils.
In the Garden. Wire is uscful for sup)porting climbing plants and trained fruit trees, and for binding joints or pergolas and arches. Ordinary wire is liable, however, to liecome sun-hot during summer, scorching shoots and tender growth. In high winds, too it is apt to tear tendrils and young branches. Multi-stranded wire wiih a composition covering is best suited for garden use.
Wire Gauges. Gauges for measuring the thickness of wire are made in several shapes, and there are a number of different systems employed in measuring. The thickness of the wire is denoted by numbers, except in the case of the Lancashire stecl wire gauge, in which letters are used. In most gauges the lowest number indicates the thickest wire, but in the Whitworth gauge the reverse is the case. The Whitworth gauge ranges from 5 in. (No. 500) to 001 (No. 1), and it has the advantage that the number of the gauge is a key to the dimension. In the other gauges in ordinary use the number is no indication of the size of the wirc. The British imperial standard gauge, indicated by the letters S.W.G., is the English legal standard for measurement, and its graduations extend from $7 / 0=\cdot 5$ in. to $36=0076 \mathrm{in}$., and include 43 numbers. The Birmingham wire gange is still in general use, and many wires are quoted as B.W.G. Its numbers range from $00004 / 0$ to 18, and with slight lifferences in the

aecond and third decimal point from 19 to 36 . Wire fromthe United States is mensured by the Brown and Sharge (B.\&S.W.G.). The disk gauge is gencrally used, being more convenient than those of oblong shape. See Fence; Gauge; Micrometer.

## Wireless Reception: The Choice of a Set

## Different Types and Their Leading Characteristics

The component apparatus are severally dealt with in this work under numerous specific headings, e.g. Value, and the complete receiver is discussed in detail under Broadcas Receiving Sets. Other contributions describe the accessories, e.g. Accumulator; Rectifier Sec also High Tension; Reaction; Selectivity

In the early days of broadcasting the hoterodyne and the short-wave receiver, must prohlem of wireless reception was, in one alro be considered The superheterodyne en sense. simpler than it is to day, because all the designer of a radio receiver had to hother about was the question of range There was no need for selectivity as the mumer of broadcasting stations was small. With the improvement in the efficiency of the valve ( $q \vee$. ) and also in coil design, distortion in reproduction and instability on the highfrequency side made their appearance.

The introduction of the screcn grid type of H F ralve overcame most of these difficulties.

Unfortunately, however, the screen-grid value did not fulfil its carly promise of selec

made to work successfully as a tigh-frequency amplifier on short waves Later, the knowledge gained from the development of the modern superhere:odyne for use on the ordinary broadcast waveband was applied to the solution of the short-wave problem. with the result that the superheterodyne, has now decinitely talien its place as the best form of short-wave receiver.
Single-Circuit Tuning Sets. There remains yet one more class of receiver which has hitherto not been mentioned, and that is the type using cascaded single-circuit tuners giving a high degrec of selectivity coupled with the incritable distortion caused by the resulting attenuation of the upper masical register. This distortion is "corrected" by n specially designed low frequency amplilicr, in which the attenuated frequencica are boosted up

It will, naturally, be appreciated that this method of obtaining distortionless selectivity is in direct opposition to the band pass principle which, as its name implies. "passes" the complete range or band of musical frequencies sent out by the transmitter. without any attenuation, so that no subsequent "correction " is necessary.

Choice of a Receiver. For those who contemplate purchasing or tuilding a modern instrument, it is necessary. first of all, to make quite clear the essential difference between a battery-operated and an "all-mains" receiver Apart from its obvious advantage of enabling all batteries to be dispensed with, the mains-driven receiver is more sensitive, and capable of greater output without discortion. This is due to the fact that the power obtainable from mains is not only cheap but also abundant, and it is possible on such receiver to use special
tivity. and, although its characteristics were gradually hettered, little was done to improve selectivity until designers turned their atten tion once more to the tuning circuits and eventually evolved the modern band-pass tuner, which not only solved to a very great cxtent the sclectivity problem, but enabled this very desirable fenture to be obtained without the loss of quality hitherto associated with it.

Power-Grid Rectification. Side by side with the developments enumerated above, efforts were mate to secure the best possible reproduction by the removal of various other causes of distortion In particular, the detector has been improved beyond all recog nition by the gradual evolution of the powergrid method of rectification, which calls for rather special values of grid condenser and leak, 0101 mfils. and $\cdot \underline{5}$ megohins being the values usually recommenderl. An H.T. supply voltage of not less than 201 is also necessary to maintain the rather high plate current value of the power grid detector, normally about 8 millianperes.

Owing, bowever, to its extravagance in the matter of H.T current consumption, the arrangement mentioned is really only suitable for those having mains at their disposal, and the same thing is true of many modern output valves. It musi not be thought however that this means that the battery nser is compelled to put up with distortion. It merely means that those having acces to supply mains are able to get somewhat better results, and presumably always wil be able to do so. In actual fact, the battery user has little to complain of since the recent clevelopment of specia! power pentode valves intended for battery use which have exceedingly low-current consumption in view of their exiraordinarily ligh undistorted power output.

The Superheterodyne Receiver. Two im portant classes of receivers, namely, the super
 valves having an indircetlyheated catliode, whereas if the power supply is restricted to batteries, the running costs of these valves would be prohibitive.

Those who desire to receive only theallernativeprogrammes of the local Regional transmitters need have no more than a simple two-vnlve receiver of the regenerative detector type, which even at very close range will be capable of completely separating the two transmissions. Those who desire programmes other than
highly specialized instru ments, employs only tive or six valves The frame aerial is no longer essential to secure selectivity, and its place has been taken by the mains, which are employed as an acrial as well as suppliers of encrgy. Whe" extreme ranges are desired, or when local receiving conditions are bad. an ordinary "open" aerial and earth system can be employed.
Short-wave Receivers. It is well known that short-wave reccivers, under favourable conditions, can bring in stations from the uttermost. ends of the earth with a simple two-valve arrangement, provided that a critical degree of reaction is used. As more and more short-wave stations sprang up there came a demand for greater reliability and greater simplicity is tuning, and tin. ally the screen grid valve was pressed into aervice, and really

Wireless. Fig. 1. The chassis for a modern battery operated superheterodyne receiver with one-dial control and band-pass tuning. Figs. 2 and 3. Showing a compact short-wave superheterodyne wave-band. This set is ftted with an interchangeable coil boxas
wale wave-band. This set is ftted with an interchangeable coil box Courtesy of 'Wireless World
that of the local station or who live some distance away from a broadcasting station, should choose a set having a yood high: frequency amplitying stage, or if extreme ranges are desired. a set having two or more stages of H.F amplification. A two-valve receiver should not be used for bringing in distant stations, even though it is capabile of doing it, the reason is that in most cases the sensitivity necessary for the successful reception of statione other than the local will call for a degree of reaclion which is incompatible with good quality. Apart from this, excessive use of reaction causes oscillation and leads to interference with other people's reccption.

The man who wants an ambitious receiver will naturally choose the superheterodyne. lt is by no means impossible for a superheterodyne to be used with batteries, and several designs are available in which by a judicious selection of valves, running costs have been kept down to a minimum without seriously undermining the performance of the receiver It must be admitted, however, that this type of receiver is one which is more likely to appeal to those with an electric supply.
Portable Sets. When one is considering the question of a portable receiver, it is a mistake to choose a set because of its exceptional lightness. A fair amount of weight in a portable, if it is by a good maker, means a suhstantia! type of H.T. baltery and, there fore, economy in upkeep.
Interference Troubles. With regard to ex traneous noises coming in from every conceivable form of electrical npparatus ranging from n tram to a fan, it will be found that the more sensitive the set, the greater the trouble from interference. The use of a frame aerial or the abandonment of the earth connexion in favour of a rough counterpoise will occasionally mitigate the evil, but in most cases the trouble can only be cured at the source

Interference from atinospherics is also n source of considerable trouble when attempt. ing distant reception, more especially in the summer, and there is no remedy at present available Atınospherics seldom interfere with the reception of the local or nearby stations, however, except in thundery weather, as the ratio of signal strength 10 atmospheric noise is overwhimingly great. $\mathrm{U}_{\mathrm{p}}$ to a point the same statcment holds good in the case of interference from electrical machinery, but the source of interfarence is oftes within a short distance of the receiver, and does not originate several hindreds of miles a way as is frequently the case with atmospheric disturbances.
Wireless Licence. In Grent Britain a licence must be procured before a wireless receiving set miny be worked. It costs 10s., and is valid for a year from the date of issue. In addition to n stationary receiving set, locnted at the licensce's address, the livence covers one portable receiver. The portable set must not be worked by any person other than the licensec or a person residing in the licensee's premises, and the licence must be carried by the person working the portable set. The apparatus must not be used in such n manner as to cause interference with the working of other stations. In particular, teaction must not be used to such an extent as to energize any neighbouring aerial.

The combined height and length of any external aerial must not be more than 100 feel. The apparatus must not be used for the receipt of messages other than those intended for receipt thereby, or sent out, for general reception Should any other message be unintentionally received, the licensee must not make known or allow to be made known its contents or origin, destination, existence, or the fact of its receipt. Such a message must not be copied, reproduced or made use of
WIRE NETTING: Its Uses. Galvanized wire netting is useful for a varicty of purposes.

It is obtainable in rolls of 50 ft . length in and examined every few days. If it is desired widths from 1 ft . to 6 ft ., increasing by 6 in ., to poison the wireworms. the slices of root, and with meshes varying from in., increasing or preferably smail pieces of rape cakr, may by $\frac{1}{8}$ in. to $\frac{3}{4} \mathrm{in}$, by $\frac{1}{4}$ in. to $\frac{1}{2}$ in., with addi- be dipped in a mixture of Paris green in tional sizes of $1 \frac{1}{8}$ in., 2 in ., 3 in . and 4 inf . In water ( 1 oz . in 2 gallons) and ther buried. the large mesh the selvages are 3-ply, otherwisc it is usial to have 2-ply twisted selv ages. Netting of 3 and 4 in. mesh can bc obtained in wilths of $3 \mathrm{ft} ., 3 \mathrm{ft} .6 \mathrm{in}$. and 4 ft ., with a 3 -ply twistexd selvage at the top and bottom and a 3-ply strand woven in the centre. Mixed mesh wire netting is made up of two widths laced together and afterwards galvanized.

The gauge of the wire used in the netting depends on the size of the mesh; except the sniallest mesh, which is gencrally No. 21, all sizes can be obtained in several gauges. The best quality should always be purclinsed.
In securing wire netting to framing, it is generally advis. able to fasten one of the selvage edges lirst, straining it as tightly as possible. The opposite edge is similarly secured, leaving the ends to be neatly turned in and secured nt frequent intervals. In using wire netting for fencing, it can be attached to stakes of wood or iron, the latter being generally nore convenient and lasting. Stakes should be placed at intervals of from 6 ft . to 9 ft . apart. Wooden stakes should be round for preference, pointed, and entirely creosot, failing this the

The adult beeties may lee trapped in spring and summer by means of small heaps of cut clover, sainfoin, or broken rape cake covered with a tile. See Insecticido.

## Tomnto.

WIRING DIAGRAM. This piece of mechanism is a pistorial or practical representation of the connexions to the various component parts of a circuit, as distinct from a circuit diagram, which latter is simply a theoretical conception. IIn wircless the wiring diagram may take the form of a blue print, or alternatively a black and white drawing to scale, the panel and baseboard usually being shown in plan and the components in their correct rela. tive positions. The circuit connexions are then indicated by means of lines joining the terminals on the various components. Set Circuit 1)iagram.
WISTARIA. This is onc of the most beantiful of all hardy climbling plants. It is seen to the best arlvantage on antarch or pergola, though it may be planted against a wal!: it is verystriking when trained on a circular trellis in the open gardet. This shrub thrives in ordinary exp wood should lie coated with tar and the exposed portion treated with a wood preser. vative. Sawnstakes, unless of stout material, are liable to snap. Iron stakes of circular section are obtainable provided with an extra prong for fixing in the ground. They are made in several lengths, giving a height above ground ranging from 18 in . by 6 in . to 6 ft . and 7 ft ., with thicknesses varying from in. to $\frac{8}{4} \mathrm{in}$ diameter. For strong fences 1 in angle iron is obtainable in lengths of 4 ft . or 4 ft .6 in ., and 5 ft , with riveted plate for pressing into the ground with the foot, and a hook top and bottom for holding the netting in position. See Aviaiy; Chicken; Fence; Poultry ; Tennis Court, etc.

WIREWORM. This word is eniployed somewhat lonsely for pests that attack crops. True wireworms, however, are the young of certain species of the elick beetle or skipjack, and are easily distinguished by their yellow colouring. They are common and very widely distributed.
To combat this pest the following hints are givesn in Leaflet 10 issued by the Ministry of Agriculture. If it is not desired to use a propristary compound, experiments may be made in the use of naphthalene alone. "This substance in the crude or semi-refined form can be obtained from gasworks or makers of insecticides. The nuphthalene in powider, at the rate of from 1 to ? oz. jeer $\mathrm{sig}_{\mathrm{g}}$, 叉d., should be worked into the soil as thoroughly as pos sible, and its effects stem to be inuch greater if the application is followed by a heaver rainfall or drenching by artificial means.

If the land is not badly infested, or if soil insecticides are considered unsatisfactory, wireworms may be either trapped ot dealt with by poisoned haits. In the former case pieces of potato, beet, or carrot should be spitted on short sticke, buried ir, the ground,
soil; it is rather slow growing for the first year or two. The way to prune is to allow sufficient shoots to develop to form the main branches and to shorten the side shoots in summer und again in winter to ensure the development of blossom buds.

The common kind is Wistaria sinensis One with longer Hower bunches is Wistaria multijuga ; this provides a remarkatle display when trained on a pergola. Both have lilac-mauve blooms in carly summer. The white variety of multijuga is particularly beautiful. Wistarias grown in pots can le forced into bloom in the greenhouse in spring. See Climbing Plant: .Japanese Garden; Roof Garden

WITCH HAZEL. This is the popular name of a group of leaf-losing, autumn, winter and spring lloweriny shrubs of which the botanical name is hamamelis. They are slow

Wistaria. Beautiful drooping racemes of the species sinensis, one of the most valuable of all climbing shrubs. See article above
rowing, but eventually form large bushes. Ordinary soil suita them, and they need very little pruning: it is necessary merely to thin them out occasionally. The best is Hamamellis mollie, which bears frugrant pale yellow Howers in mid-winter: arhoren has deep yellow Howers in Februay and virginica bears rale gellow hlooms in late autumn. They are most interesting and easily managed hardy shrubs. L.ayering is the best method of propagation.
Medicinal Uses. Witch hazel is an active hacmonstatic much used for controlling blecding. A few drops of the liquid extract in water snuffed up the nose :s an excellent treatment for nose bleeding. Hamamelis, on account of its astringent action, is a useful home remedy for hapinorrhoids.
WOLF. The fur of the wolf is longer and coarser than fox, but it is also cleaper. The wool ies soft and very liable to felt, but on the whole wolf wears fairly well and is less frapile than many of the more expensive pelts The colour varies from yellowish grey to blue, but some skins are ao dark that they almost apprar to te black Th.e general directines given for the care of long-haired furs may be applied tos wolf See Fur.
WOLFHOUND. The three varietics of this dog that are most usually seen in Great Britain are the Alsatian, tho Irish and the Borzoi. See Alsatian; Borzoi: Dog; Irish Wolflound Kennel, etc.
WOLVERTNE. The fur known as wolverne is obtained from the carciaiou or skunkbear. It is soft and thick, and of a dark. brown colnur, a whoic skin usanlly measering 3 to 4 ft . in length. A patch of dark fur in the centre of the back is known as the sadille. Around it there is a band of lighter fur, and then another dark ring. the latter ia not quite so dark, however, as the saddle, which risembles fine sable tail, and is usually cut out and used for the same purposes. After the sarldle has been removed, the gap is filled with bearskin, and the whole used for rug. making.
WOOD. Wood as used by the cabinet maker and the woodworker in general is the seasoned product of the timber tree. and as such is divided into two classes, roftwoods and hardwoods. It is usual to describe as softiroods those obtained from trecs bearing needlepointed leaves, and to classify as hardwoods those from trees bcaring hroad leaves. Only a very small quantity of the wood used in this country is home grown; the main supplies come from all parts of the world, gencrally cut into recognized sizes and partly seasoned.
The principle varietics of timber are dealt with in this work under specific headings. Other information is given under such head!ngs as Grain ; Timber, etc. Surface treatment is described in Paint; Stain; and Varnish.
The most commonly used wood is known as deal, but this is the name of the size into which several varieties of pine or fir arc cut. Under the one species of pine there are several entirely different woods, ranging from one of the softest to one of the hardest. The same difference is found among the hardwoods; for example, lime is soft and even textured, and lignum vitac is exceedingly hard and difficult to work.
The matter of shrinkage is of importance in all forms of cabinet making, and it can be taken as a general rule that the softer the wood the more liable it is to shrink. There are other faults which generally go with a liability to excessive shrinkage. Anong them are shakes. These are splits in the direction of the grain at right and other angles to the annual rings as well as along the line of the rings, the latter being known as cup shakes The pines arc liable to knots, and it is rarely possible to obtain a board of yellow deal with. out knots, but if they are only small it does
not matter very much; large knots, however are liable to fall out, especially in thin boards.
The difference between heartwood and sap wood can generally be noted by a difference in colour and in the brilliancy of the planed wool. The heartwood is the fully developed portion of the tree, and the sapwood is only partly lignified. Satin walnut is a case in point for the iree produces very wide sapwood which is imported under the name of hazel pine. The heartwood of ycllow deal is of a bright golden colour and has a distinct lustre while the sapwood is of a bluish shade and planes up to $n$ rough spongy surface.

Timber for Carpentry. The timbers used for carpentry are mostly softwoods, such as red deal, white deal or sprice, and red or yellow pine. Red deal is in gencral use for window frames, cold frames, doors, and similar out. side work which is to be finished by painting White deal is used principally for flooring boards, tongued and grooved partition work, and common inside tixings, such as shelving The better type of work, such as table tops, the ends of cupboards, pancls, ctc., calls for a medium quality of yellow pine. Tongued and grooved inatchboarding and Hooring boardy are sold by the square, a square being nomin ally 100 sq ft; but amaller quantities may be purchased at per sq. yd White deal shelv ing, machine-planed on both sides and both cdgce, can be obtained in varying widths from 9 to 11 in wide at per foot super.

There is a large variety of ready-made mouldings for picture rails, hat and coat rails, cornices, sash hars and skirtings; these are obtainable at the rate of per Jofl for small quantities of mixed woods, such as mahogany, walnut and canary, the amatcur is advised to purchase what are called cuttings at the local manufacturing cabinet shop. Some kincls of wood are obtainable in wider widths than others. For example oak is not generally obtainable in wider widths than 11 in. and avernges 8 in . wide: satin walnut averages 9 in., but can be obtainer if in wide. Black walnut a verages 7 in , and is obtainable up to 11 in., while American whitewond and nahogany. with an average width of 10 in ., are available up to 23 and 24 in . wide Yellow dral does not run more than 11 in., but Oregon pine is easily obtainable in widths up to $2 f$ in. It does not follow, however, that the wider widths are more suitable for all wide work, for it is often an advantage to glue up several narrow widths as they are then much less liable to warp.

Colour and Grain. The colour of the wood is another consideration in the choice of wood and in this respect there is great variety. A choice can be made from the alnost pure white woods such as sycamore, spruce, and holly, to the black of ebony. Yellow woods are numerous in both soft and hard varietics, e.g. ycllow deal and boxwood. Red woods include red pine, sequoia, radouk, mahogany, and rosewood. Brown woods are obtainable in the form of satin walnut, chestnut, and snakewood, while walnut is of a purplish tint
In addition to the actnal colour of the wood, the peculiarities of the grain enter into considerations of choice, not only the distinguishing grain of the wood, but the accidental formations and inalforinations. As a rule, any wood cut parallel with the diameter is even in grain and when there is a difference between spring and autumn growth, as cxampled in yellow deal, this contrast of colour can be accentuated by cutting the wood at rarious angles. The commonest example of the cross grain cutting of wood is scen in the silver grain of oak, which owes its effect to the method of sawing the woor diagonally to the medullary rays, those lines of hard cells which radiate from the centric of the tree.

The burr cllect in such woods as wh!nut amboyna, and thuya is produced by the growth of small branches on the lower portion of the trunk, which do not pierce the bark. A type of figuring known as the curl is caused hy the natural llow of the grain, which originates at the commencing growth of a branch. The grain effect in the pollard oak and other woods, as well as in bird's-eye inaple, is due to malformation ; in the former casc it is duc to a fungus growth, and also by cutting the branches close to the trunk, and in the latter to the ravages of a boring insect. It will be seen, then, that the figuring of wood is due either to the method of conversion, which is often wasteful, or to mallormations, which are rate.

Surface Treatment. Owing to the comparatively porous nature of the grain, the un treated surface of wood is liable to discase especially when exposed to damp. External constructional work should be cither painted or coated with a wood preservative, and all internal woolwork, in cases where it is not usual to treat in this way, should be kept dry and surrounded with a current of air.

Wood Ash. See Fertilizer.
Woodbine. See Honeysuckle.

## Wood Carving: Principles and Practice

## With Some Beautiful Examples of this Decorative Work

The amateur, whether man or woman, will find much scope in this handicraft for manual dexterity, skill and arlistic expression, while it can be carried out with an ir expensive equipment. Furthe assistance can be obtained from perusing suchentries as Gouge; Grindstorie; Tools; Wood

Wood carving is the one branch of sculpture that the amateur craftsman can follow with little expense and considerable chance of success. It is not, however, gencrally con. sidered as an end in itself, but as a means of decorating wood. Chip carving is a simple method of decoration. In this article he methods of dealing with carving in the round or in high relief from the simplest beginnings will be dealt with.

The heginner will be well advisod to purchase tools as they are required, and, although most of the tools illustrated at Fig. l are essential for advanced work, there is no need to purchase thein all at once. Much preliminary practicc can be obtained by the use of a tirmer gouge and a veiner, and with the former tool a series of cuts should be made on a piece of even-grained woorl, as shown at Fig. 2. It does not matter very much what the size is, anything from $\frac{3}{8} \mathrm{in}$. to $\frac{3}{4} \mathrm{in}$. will do, but lines should he made on the wood as a guide before
the cutting is commenced by the worker. The simplest cuts arc made by pressing the gouge into the wood in a vertical position. The gouge is now set back $\frac{1}{\frac{1}{2}} \mathrm{in}$. and inclined slightly backward, this having the effect of removing a chip of wood of segmental shape. This is followed by a similar commencing cut a little farther back, with the distance of the second cut increased. Several cuts should be made thus, each time increasing the distance until it is possible to scoop out a space of 1 in. long up to the first vertical cut talien.

On slowly turning the gouge round on its own curve, a circular cut can be made, and when this is accomplished the scooped cuts can be made each side, as at A and B, Fig. 2. A pattern combining the first and sccond methods is shown at C and D.

The next stage is to cut a circular space and combine it with the cuts at $D$ to form the patterns at $E$ and $F$. The use of the veiner in conjunction with the first practised cuts

Wood Carving. Fig. 1. Selection of tools which are necessary to the wood carver Courlesu of The Manual truinina Toal Co (Shelfield)
enables a variety of patterns to be formed, as indicated at $G$. This provides an effective method of wood decoration.
Another form of pattern is shown at H , and is more difficult, but with a perfectly sharp gouge the cuts can he made quite clean. It should be noted at this stage that a considerable a mount of early carved decoration was effected by the ahove means, and numerous examples can be seen on old chests, settles, and other furniture. Most of the cuts illustrated at Fig. 2 are done in the direction of the grain, but practice in other directions of the grain must he acquired when some confidence has been gained in the use of the gouge
The licen edge of the tool soon becomes dull, even when working with softwood. and unless the keenness is frequently renewed it will be impossible to obtain clean cuts.
Owing to the extra licenness required, a leather strop or two should be provided, so that the sharpened edge can be stropped Leather helting is useful, one piece being thick, and the other thin enough to fold so that it can conform with the inner curve of the tool.

A Simple Panel. Having hecome proficient in making simple gouge cats in all directions, a simple pattern form, as at Fig. 3, may be attempted, and for this purpose a parting tool and a llat gonge will he required. The shape of the centre diamond space with the triangular corners should be drawn out first, and the work can be sciewed to a small block of wood so that it can he placed in the vice. Generally the height of the bench is too low for convenient carving, and it will he convenient to make a stand with 1 in . or $1 /$ in wood.
The first stage in working out the pattern at Fig. 3 is to outline the inner parallel with a parting tool. The wood should be cut away to the centre hoss with the flat gouge, and then the hoss can be shaped with the latter tool. The leaf formation is indicated with the parting tool, and with the addition of the veiner the whole of the work can be effectively done.
It is a good plan to endeavour to do as much cutting as possible with the fewest number of tools, and if the pattern can be effectively done with the above mentioned tools much valuable practice will have been accomplished. A further example of simple carving is shown at Fig. 4. This is a spray of oak leaves with a few acorns

The first stage after the drawing has been transferred to the wool is to cut out the background and leave the pattern standing out.

In the first place, the outline should be cut down with a vertical cut, and the waste removed with a flat gouge. It will be seen that
e stalk of the lower acorn is missing. This is the result of careless outlining. In approaching a thin stalk, the lirst cut sliould be at least $\frac{1}{8}$ in. away from the required line, and the ground should be removed before the wood is out back to the correct line. If this is omitted, it is quite possible for the gouge to slip and entirely remove all across grain stalks, or, if it does not actually cut into them, the grain may he sufficiently raised to cause them to break off in the subsequent finishing.

The leaves should be finished with a veiner, and a slight amount of modelling effected with a flat gouge. A development of this form of work is shown at Fig. 5, which is an adaptation of a piece of early wood carved ormament. The design is quite straightforward, but a gouge or two with quicker curves should he utilized. The ground is stamped with a punch to provide a suitable tinish, but this should not be overdone, as it detracts from the general effect in some kinds of work

Bold work with broader cuts should now be attenipted, and a good example is shown at l'ig. 6. The wood should be of even grain about 12 in . by 9 in . or 10 in . by 7 in , and 1 ! in thick at least. The pattern should be marked out and then cut down, leaving the pattern standing out. The first stage is to cut the inner portion down and then the top and hottom portions, leaving the two side leaves to be roughly shaped with suitable gouges and flat chisels. In work of this description each portion should be roughed out in turn, making no attemplt to obtain any finish until the general shape of the curves has been worked. A

Fig. 2. Preliminary cuts with gouge and veiner, showing method of forming a simple pattern. Explanations of the lettering will be found in the text tools in the suggested outfit.
at the top of the curves will be necessary, but the finishing of these portions should be left until the top rounded portions of the work are practically tinished
This exercise is to gain command over the tools, and not primarily to produce a piece of ornament. The left hand should be used just as much as the right, for the latter will hold the tool and give the necessary guidance to it, but the left hand is essential for purposes of resistance. Sweeping cuts with both gouge and chisel should be practised, and considerable skill will be required to enable the tool to be stopped before the cut becomes deep and perhaps begins to pull the grain apart. This must be avoided or inlinite trouble may be caused. It is in the latter that the left hand will be most helpful, and it can be taken as a general rule that the tool should never be driven forward with one hand without apply ing the counter-resistance of the other

Another important point which experience will teach is not to put too much force on the tool when working in the direction of the grain, or near a delicate piece of cutting, the method heing to remove the material by a scries of small cuts. Another use of the exercise is in enabling hine carver to give texture to the surface.

The finishing cuts on the rounds should conform to the main direction. This is not so evident in the photograph at Fig is. except in the swcep of the hollows, lut the main idea of the finishing marks should be to convey to the eye the main form of the shape.

Preliminary practice in the formation of curved surfaces can hardly be carried to excess. It is the best means of obtaining a command over the tools and gaining an intimate knowledge of the material. The shaping of leaves, as shown at Fig. 7, indicates a line of work which provides invaluable experience. The general method of tackling the outlining is the sams as in the previous example, but the great variety of curves, running in all directions of the grain, should provide opportunities for the use of all the

In dealing with the carving of natural forms, much depends on the position of the finished work, and as the carver is limited by the grain of the wood in exactly imitating many forms, it bccomes necessary to utilize the ellect of light and shade. It is impossible to represent exactly any natural form in wood by means of carving tools. Some slight alteration here or there must be made to conform with the limitations of the matcrial and with the effect of light and shade, so that the representation must be conventional. The beginner, modelling leaf and flower shapes, need not conventionalize to any extent until the difficul. ties of technique have been overcome. The laurel leaf, shown in Fig. 7, is capable of providing unlimited surface modelling.

In working out the shape, the first stage consists in forming the main slape and cutting away to form the hack. ground. The main direction of the curves shoula be roughed out with suitable gouges, and the final shaving effected with suitable llat gouges and chisels. The lightest possible touch should $J_{x}$ used, and the tool held in complete restraint as

Wood Carving. Fig. 3. Simple panel which will glve the amsteur practice in the use of a flat gouge and parting tool
a veiner, and then to ornamentation, and the lowness of the relief work each side to the does not detract from the shield, which is the approximate depth main object.
The beginner, unless The surface finishing of all parts should be thoroughly conversant with the formation of the lenf. should work from an actual cast, or at least a photograph of a finished piece of work. Failing this. a pencil drawing can be used if the effect of light and shade is shown.
An clahorated form of the same kind of leaf is shown at Fig. 9 ; it introduces animal forms treated in the more or less grotesque
shown. This is particularly required when approaching the edges of the leaves, and as far as possible the shape should be completed on the top surface before the undercutting is attempted. The exact position of the tool cannot be stated, os it should be changed cut by cut to conform with the direction of the grain, hut in the main the fibres of the word should be sliced

All cuts should be made entirely with the hands directing the tool, the mallet being rescrsed for such work as outlining and cutting out large nuter surfaces. Some very hard woods may require such pressure that is beyond hand power to perform : but, generally. if the tool is kept perfectly sliarp, and small, thin cuts are made. there will be no need for mallet work

Where necessary the left hand should hold the chisel and continually restrain it, while the mallet is usod to give a number of light taps. Nothing in the way of heavy blows should he allowed, even with the hardest woods. It is far better to attend carefully to the keenness of the cutting edges of the carving trols The conventionalized treatment of leaf forms is shown at Fig. 8, and work of this sort makes an excellent exercise for the beginner It will be seen that the main line of the con

manner so often scen in medicval work. In this exainple the curvature of the leaves renders the carving much more difficult, and incidentally provides excellent practice in the control of the tools in finishing the surface.
The best method of dealing with the panel is to form the main curves without attempiting to do any of the actual shaping, either on the surface or on the edges As much of the ground as possible should be removed, keeping it llat. and in this con. nexion it is an advantage to use a strip of thin wood to rest across the panel from side to side, and to drive wire nail through it, to project when filed off Ilat, to the reqnired depth. This rough depth gauge can be used in all positions, and will help in obtaining an even surface. The curves leading to the tips of the serrations of the leaves should be made as flowing as possible, and although a distinct depth is necessary. it should not be overdone. The raised portions of the edgos should he slightly undercut, in order to emphasize them, but generally the a minunt should not exceed $\frac{1}{\frac{1}{8}}$ in

It should not be necessary in continuing the exercises in carving to use n plaster model, and, with a view of training originality of treatment. the better plan is to work from a drawing shaded with charcoal or crayon. Assistance can be gained by studying carvings in museums, and by making pencil sketches of details.

The shield at Fig. 10 is an example of finished surface modelling. and the craftsmanship involved forms a valuable training The leaf horder should lie done first and carried to not more than $y^{\prime \prime}$ in. deep, ns the whole effect is one of low relief The horder is well filled without an excess of carried out as smoothly as possible, and, however carefully the shield itself is linished and curved, with the use of scraper and possibly glass paper, the tool marks on the foliage should not le ohliterated

Decoration of Furniture. The application of carving to furniture will be the main object of the home craftsman in learning the craft, and some appreciation of the particular form required is necessary. The florid decoration of the so-called dark oak antique furniture should be avoided. Many examples of excessive carving can often be seen, and in these cases the furniture in question has been made with the idea of providing as much carving surface as possible.

The piecc of furniture on which it is desired to execute carved ornamentation should be designed primarily for its correct purpose, and the carved decoration should be sccondary and not prominent. Small carsed panels in a framed door may be made entircly decorative and yet, on the other hand, by the use of unsuitable designs, the cye will not be able to take in the proportions and lincs of the framing. but is attracted by the weight of the decoration. It is difficult to say exactly what proportion of the space should be lecorated in any article of furniture. this is a matter of training in the laws of design and the appreciation of good form, but the first cesential is restraint, the second being proportion.
Many beautifu: examples of wond earving can be seen in old oak chests where the stiles and rails only are carved with a simple patterı in gouge cuts: in other chests the panels only are carved, the rails and stiles giving an idea of solidity and strength. The classic style of ornament is valued by many woodcarvers as providing a suludued form of decoration, and the example of acenthus-leaf ornamentation at Fig. 11 is a type of what can be done

Animsl and figure forms in the round should not he attempted by the amateur craftsman without some considerable preliminary work in modelling. A sculptor finds it necessary to use clay to enable him to a ppreciate form, and, apart from the technique of dealing with the materials, there is very littlc difference between the stone and wood sculptor. The stonccarver works on similar lines to the woodearver, and generally would be unable to tackle the figure, although a head, particularly a grotesque head, may be attempted

Many woods are suitable for carving, but they sliould be of even and uniform grsin, free from knots and shakes, and have been thoroughly seasoned. The grain should be as close as possible and free from strong markings. Of the softer woods mone suitable to the beginner, but still useful for many forms of carting, arc yellow pinc. American whitewood, hasswood, lime, and Kauri pine, and of these gellow pine will le found the best for

Wood Carving. Fig. 7. Method of using a fat ROuge in shaping natural forms, such as a leaf
preliminary work. Of slightly harder woods there arc sycamore, satin walnut, beech, and holly, and of hardwoods, onk, walnut, and sometimes mahogany can be used.

It is generally casier to obtain suitably scasoned yellow pine, and if used in at least 1 in . thick ness no trouble should be experienced in working it, but it is not snitable for high relief. American whitewood and basswood are good for preliminary practice, but tools require more sharpening than is necessary with yellow pinc. Lime is not so easily procurable, hut if it is properly sawn and thoroughly scasoned it forms an ideal material for the begenner, especially when working out such examples as shown at Fig. 3. The intermediate woods can be used for the examples given in Figs. 4 and 5.

The kind of walnut known as Italian is more suitable than the home-grown variety. Much of the waluut supplicd by timber merchants is sawn so as to show the figured grain, and this is especially evident in the English wood. The grain should be as close and as straight as possible, and wood for carving must be cut from the heartwood, sapwood being distinguished by light streaks or markings. The wood is nore suited to lowrelief carving, hut with selected specimens it is possible to obtain effective high relief.

As a rule carring should not he polished ; the only treatment allowable is that of oiling or
place of a skewer. The pinions slould always suberosa, with greyish leaves and pink llowers be cut off at the first joint. and the feet is a charming little spring flowering plant crossed after the lega have been secured excellent for the rock garden, where it should in place. The bird is cooked undrawn and be set in very gritty soil must never be overdone.

Roasting is the usual methorl of cooking woodenck. After trussing, hrush the bird all over with oiled butter, then tie over the breast a slice of bacon, and roast from 10 to 15 inin ., hasting frequently. Woodcocky should liang when rousting with the feet downwards, anul a piece of toasted bread should he placed underneath for the purpose of catching the trails. If hanging the birds to roast is not possible let them rest on bars in a baking-tin, and in the bottom of the tin underneath the bars lay loast. The birds are served on this toast with a good brown gravy and a garnish of hot acasoned watercress and cut lemon. To carve, split the bird right in half through the centre, cutting from neck to tail, and with each portion give a piece of the toast. See Game.

WOODLOUSE. Because of its slaty colour the woodlouse is often called a rlater. Noclurnal in habit, it feeds upon plants and seedlings and may do considerable damage. When its presence is suspected nll rublish and crevices of dry wood slould be searched in the neigh. bourhood of the plants affected, and if necessary treated with boiling water. Traps may be prepared with hay-filled flower pots, the sides being smeared with treacle. Borax or beetle poison may be used, and there are also proprietary preparations.
WOODRUFF. This is a pretty low growing plant which spreads very quickly and is suituble for planting in odd corners, whether shady or sunny. It becoines smothered in smill white flowers in spring, and if planted with forget-me-nots provides a charming display. It shonld not be set among choice plants owing to the rapidity with which it spreads. Any little rooted piece pulled off and replanted will grow. Ite botanical name is Asperula odoratn; the leaves have a haylike scent whell dry. The blue wondruff (Asperula azurea) is a hardy annual 9 in. high with pale blue fowers in sum. mer; seeds are sown out of doors in sprïng. Asperula

WOODSIA. The hardy kincls of this fem require a leafy or peaty soil, and a position in shady borders or banlis. Greenhouse species are best grown in pots of peat, loum and silver sand. The plants should be placed in a shaded position, and watered freely from March till October. The maximum height of the plants is about 12 in . The liardy sorts are all suitable for greenhouse cultivation. Propagation is by division. See Eern.

WOOD SORREL. This is a pretty, low growing plant suitable for the rock garden and for sumny corners. One of them (Oxalis acctose!la), which grows wild in woods in Britain, bears white Howers in spring and is

Fragrant clumps of the pink Asperula suberosa, a favourite spring flowering rockery plant
suitable for planting in the rock garden. It is however, k:Bs attractive than two kinds from the Falkland Islands, adenophylla and eneaphylla, which have grey leaves, and pink and blush-colourel blooms respectively, and thrive in a compost of sandy loam and leaf-mould among the rocks. A popular wood sorrel which is often sern in cottage gardens is that known as Conniculata rubra. It is a low growing spreading plant with copper coloured leaves and yellow flowers. The wood sorrel is propagated by division during the spring.
waxing, and these are used to protect the surface and not for polishing.

WOODCOCE. The season for woodcock extends from August to March. In choos ing a bird press the breastand pinions: the fect, also. will be supple if the bird is fresh and in good condition, the head and throat clean and the Hesh firm. The bird does not usually weigh more than llb. It is pre pared and trussed like the snipe, with the head left on and the long beak thrust through the legs and body in

Figs. 8 and 9. Methods of treating conventional forms. Fig. 10. Shield with low relief border carried out in a conventional design Fig. 11. Showing the method of treating the classic form of the acanthus leal in wood

## WOOD TURNING FOR THE BEGINNER

## The Use of the Tools and the Results Produced

The important operation of Turning is described in this work under two main headings, each corresponding to one of its branches. Thus the manipulation of metal is dealt with in the arricle Mctal Turning. See also Lathe: Mandrel, and the many articles that deseribe items of furniture, etc., the component members of which are turned, e.g. Candlestick; Chair; Table

Wood turning consists chielly in fashioning tool is V-pointed and ground and sharpened wood to circular shapes by revolving it in $\Omega$ on the outside of the $V$. lathe and applying cutting tools to the surface. It has many and varied applications in the home, being the only practical method of producing chair and table legs, little columins with turned bases, candlesticks and a host of other articles which are circular in section.

The amateur should commence by prac tising on such material as boxwood or heech.

Using the Gouge. The method of holding the gouge is illustrated in Fig. I, the blade being grasped in the left hand near to the cutting end of the tool. The outer part of the first linger of the left hand is pressed against the back of the T-rest, while the fingers of the left hand hold the gouge tirmly to the top of the rest. The right hand grasps and manipulates the handle. To use the gouge, the piece of worls is first lixed and the lathe started.
It is necessary to rememher that as the wood revolves it appears to the eye to be solid and circular, but as a matter of fact it will be

half-twist is given to the blade directly it commences its cut, and the tool is traversed bodily towards the headstock, taling care to maintain full control over its movements.
It is usual to terminate the cut at some distance from the chuck or face plate, except in those cases where the end of the wood is overhanging and there will be no risk of the tool catching up on the chuck The same operation is repeated with the same caution until the general diameter of the material has been reduced to its proper size, when it will be circular in section and more or less cylindrical in shape from end to end. From this stage the pattern of the object can be turned.
Turning with the Grain. To ensure turning with the grain of the wood, always work downward, as in Fig. 3, traversing the tool from the larger diamater towards the smaller. When the material has been reduced to a cylindrical shape it may be smoothed with a chisel. This should be held in the same way as the gouge, but the left thumb should be interposed between the underside of the chisel hlade and the upper surface of the T-rest, so that the part of the chisel which will actually cut the wood is about the middle part of the cutting edge. The chisel is traversed along the work in a similar manner to the gouge.
The shavings soon tell whether the chisel is cutting properly or not. They should come away clean cut, and not look as if they had been scraped or rubbed off. In the latter event, it is almost cerfain that the tool is not sufficiently sharp, that the speed of rotation is not high enough, or the tool itself is not being held in the proper manner. Quite slight variations in the position will make a big difference in the turning.
Supposing that the work is comparalively long and slender-for example, a sma!! leg for il footstool-a good plan is to prepare a full-size drawing of the desired shape. Then take a lath of wood and drive sliarppointed nails through it at those places where the shape of the ohject changes. When this is applied to the revolving cylinder the points of the nails scratch a series of rings, as in lig. 4, which indicate the points where hollows or curves are to be turned. In order to turn a hollow, as in Fig. 5, the gouge is used first from one side towards the valley and then from the other side, working downward, and compelling the cutting edge of the

To avoid accidents he must always see that more or less square the material is properly tixed in the lathe, so and running out of that there is no risk of its flying out. He should truth. Consequently, hold the tool firmly, and bring it near the by approaching the revolving wond with caution. The turning gouge to the inatools are provided with a long liandle very ginary face of the securely attached to the shank. They must material, it will, in be kept absolutely keen and sharp. A hlunt fact, only cut off the tool is a danger.

A gouge, chisel, and $V$-point or veiner are the principal tools required. A gouge ahout $\frac{6}{8} \mathrm{in}$. wide is suitable, although it is an ad. vantage to have one rather smaller, and also a thickier one. The gouges are ground on the outside of the curved part. The cutting end of the chisel is inclined and the cdge comes in the middle of the thickness of the blade. both sides being ground off to a taper and sharpened on an oilstone. The veiner or parting-off high spols or corners, as in lrig. 2, and it is at this stage that the utmost care must be exerciser!. The tool should be pointed to. wards the work and held with the blade pointing at a small angle torvards the headstock. A peculiar

Wood Turning. Fig. 1. Correct way to hold the gouge. Fig. 2. Gouge shown cutting of high spots or corners of the rough material. Fig. 3. Working downward in order to avoid splitting the grain. Fig. 4. Applying scratch gauge to show points where hollows or curves are to be turned. Fig. 5. Turning a
concave surface. Fig. 6. Parting off with chisel held vertill concave surface. Fig. 6. Parting off with chisel held vertically. Fig. 7.
gouge to describe an are of the ciecle or follow a curverl part by moving the handle of the tool sideways while resting the major portion of the weight on the hand rest. Flats are usually shaped with a chisel, and parts at right angles to the axis of rotation by holding the chisel with ita narrow edge resting on the hand rest, as in Fig. 6. The breadth of the blado is vertical, the cutting edge thus inclining bac'sward. It has to be worked very carefully, and a little cut marle on each side of the valley so that the tool will not jam in the groores. Fine lines and beadings are oftien lurned witl the point of the chisel.

If it is desited to turn to dimensions calipers should be used in the ordinary way It is assumed that the work is mounted between centres on the usual prong or fork centre or on a small face plate with a taper screw centre, screwing it to the latter or driving it on to the prong chuck with a few strokes of a mallet The opposite erd is then supported with the point centre of the tailstock, the latter being forced into the end grain of the wood and locked firmly in that position. When a piece of flat material is to be turned inlo a disk to form a base or support, the best method is to secure it by screws to a suitable metal face plate, which screws on to the mandrel nose A similar mode of chucking can be used for various aorts of bowls and similar work.

Fig. 10. Example of a simple lathe, suitable for the amateur Courles॥ ol J. Sagar \& Co.. Lld
Internal work is caried out in much the same manner as external wood turning. With a suliall bowl, for example, such as thit illustrated in lig. 7, the best plan is to tum up the centre first and work outward. The testing of the size of the work is accomplished by the use of inside calipers, but with intricate or important shapes a simple teinplate may be used and applied to the work from time to time (Fig. 8), as a check to the eye. The work should be linished with glass paper, a small piece being grasped between the finger and thumb and worked over the curved surfaces, as in Fig. 9. In the case of flat work the paper should be wrapped around a Hat wooden block or rubber and used with a slight forward and backward motion while the work is being rolated at the highest possible speed. When deaigning parts to be turned, and it is necessary to join two or more pieces loget her, the beat plan to ensure keeping them all in line is to turn a small projecting peg on the end of one part, and to bore a similar sized hole centrally in the other part. This will sarve to centre both parta and keep them in their proper relative axial line.

Choice of Lathe. The article on Lathe discusses the principles governing the design and construction of this appliance, as modified by the specitic purpose for which it is intended.
The inain considerations in a lathe for wood turning are a good headstock with bearings suitable for prolonged working at high speeds, an adjustable tailstock, and a suitable rest for the turning tools.

An example is given in Fig. 10. The red, which is flat topped, is accurately machined
and bolted to two inassive supports. On the left is the headstock, which is holted to the bed by plates passing underneath. The spindle is fitted with a four-speed cone pulley for flat belt drive. Bearings of heavy phosphor bronze are used, adjustable for wear. while luhricators are a.ttached The hand

Wood 'lurning. Fig. 8. Use ol template consisting of a piece of card or zinc cut to the correct profile. Fig. 9. Smoothink the work with glass paper before the fnal operation of polishing
rest is adjustable in every
direction, and can be fixed in lirection, and can be fixed in any position along the whole length of the bed. The T portion is sulficiently long to allow of a good sweep of the turning tool. The tailstock is of the pattern fitted to many metal turning lathes. It is adjustable as regards disposition along the bed, and has a spindle capable of adjustment by the hand wheel provided. A locking screw is also fitted. The chucks enable all classes of wood turning to be accomplished. In the main, most chucks consist of a flat disk or plate, to the centre of which is attached a steel wood screw. The chucks screw on to the mandrel nose, as is usual.

Such lathes may be driven by treadle or power, and with the latter a countersbaft of the type illustrated is necessary. This is fitted with a fast and loose pulley mechanism, and a cone pulley similar to that on the lathe itself. The countershaft should be arranged on staging above the lathe, and the belt should be inclined away from the operator The striking gear will normally come with its handle or chain within easy reach of the operator's hands thus making his task easier.

Woodworm. See W'orm.

WOOL. There are numerous grades of wool, but, generally speaking, it comes under two great divisions, morimo and cross-bred. The merino sheep is bret in Australia chicelly for its wool, while the crossbred sheep is largely bred in New Zealand, partly for its fiecee and partly for its carcass.
The two different kinds of yarn produced from wool are known as woollen and worsted, anll, generally speaking, all woven goods made from wool come under one of these two classes. lior woollen cloths the yarn is not so fine, strong or elastic as for worsteils, which require the longest fibres of wool spun into smooth yarn. Molton and pilot cloths, savonics, twects, cheviots and blankets are cxamples of woollen piece goods, while worsteds include Botany scrges, suitings, gabardines, Becliord cords and hopsacke.

For some yarns hair is used in combination with worsteds, as, for instance, camel's hair, goat's hair and alpaca. Owing to the greater length of fibre in the formation of worsted yarns, worsted fabrics wash better than woollens. The latter have a tendency to felt, anil bleaching powders should not be used, as they eventually dissolve the yarn.
Knitting wool bought in skeins is best 'e: t in that form until wanted. When winding $t$ into balls the thread should not be wound too tight. The softer kinds of wool are warmest in wear, but the harder sorts of worsted yarns last longer and shrink less. Three-ply and four-ply wools are bullier than 1 wo-ply.

Mendiug wools may be bouglit by the skein or on cards. Special wools are sold for tapestry needlework. Berlin wools are a softer, coarser kind. Very durable and heavy wools are manufactured for rug making. See Crochet : Knitting; Rug ; Shawl ; Stocking. cte.
Woolly Aphis. See American Blight.

## WOOLWORK AND WOOL EMBROIDERY

## Quick and Effective Methods in Ornamental Needlecraft

This article deals chiefly with pictorial and conventional des:gns worked in wools on linen fabrics. Solid embroidery on canvas is dealt with in the contribution on Tapcstry Needlework, end other special forms of woolwork are described under the headings Crochet; Knitting; Rug. See also Appliqué Work; Embroidery; Laid Work Needlework Pic!ur=

Used in its bronder sense, the term woolwork includes all work done with wool yarn and needles, or special hooks, from darning and knitting to crochet and knotted rugmaking. In particular it is applied to pictorial designs and necdlework pictures carried eut partly or wholly in coloured wools.

The term wool embroidery is also a broad one, covering any (lecorative stitchery in wools, but in particular the term is employed for fancy work in which naturalistic or conventional designs are partia! ly cmbroidered in wools !eaving portions of the background fabric exposed.

Woolwork pictures as carried out in the 17 th and 18 ih centuries would be too tedious for most needlewomen of to day, although smaller pictorial designs are still exquisitely worked in pettit point for bags.

Materials and Designs. Very effective woo!work or embroidery can, liowever, be quickly achieved on rather coarse linen, coloured or of an unbleached sharle, using skeins of tapestry wools, or penny balls of embroidery wools with crewel needles.

An cmbroidery frame will be necded by most workers for a solid pictorial design
such as that illustrated in Fig. I. which could be charmingly adapted and worked in natoral colours on linen for a cushion, screen or blotter panel, or framed and glazed for wall decoration. An embroidery frame cousisting of two wooden hoops would lie a suitable one on which to work a panel of small size, but if the panel is a large one the regulation embroidery (rame with rollers, on which the work can be evenly stretched, will be needed. For work of less solid design, a frame is not necessary, but to prevent puckering a good method is to pass the needle up and down through the embroidery as if on a frame.

A great variety oi transfer designs can be bought either for flowers tigure or geometrical embroidery or many different

Woolwork. Fig. 1. Pictorial design of polyanthus grouped in a bowl worked in natural colours on grey linen. Fig. 2 Details for working fowers and leaves. The dower on the ripht is embroidered in atin stitch, that on the left partly in long and
short stitch and partly in satin stitch
ideas can be utilized. Flower, bird, animal or Japanese prints can be traced and transferred by means of carbon paper to the material to be embroidered. Dircctions for transferring designs are given in page 418.
Interesting conventional designs can be worked out by pencilling the outlines of coins to mark rounds tor Howers and evenly spacing a number of these on u piece of paper the size of the work, then transferring the drawing to the material. Larger Howers can be worked in buttonhole stitch with an inner ring of chain stitch and centre of French knots. Smaller ones in lazy-daisy stitch and rose stitch. The intervening spaces can be filled in with trellis (q.v.) stitch, or with diamond or diaper stitch (see page 684). Instcad of work ing these dcsigns al over
a cushion, bedspread or duchesse set, they may be enclosed in a circle made by drawing round a plate of the size requircd and outlining the edge of the circle with chain stitch in black wool bordered with back stitch. The rest of the work can be speedily carried out in l3erlin wools in Victorian shades of bright blue, grass green, nagenta and foxglove pink, and can be done on felt or hessian, crash, rattine or linen.
Most of the stitches used for woo!work are given in the page of stitches illustrated in the article on Enibroidery. When starting a piece of work it is a good plan to select the stitches which will be most useful tor the various portions of the dosign. Fig. 2 shows the stitches which may be used for the polyanthus tlowers and leaves in Fig. 1. The flower on the right can be worked in satin stitch. as shown, and then outlined in back stitch; that on the left in long and short stitch on the outer portion of the petals, and with satin stitch in different shades for the inner portion and centre. The leaves can also be worked in satin stitch, with the veins in stem stitch, back stitch or crewel stitch, in a darker shade of green. The bowl may be outlined in crewel stitch with one or two lines of sbading. Each group of Howers is worked

in one ol two ways; a glance at lig. 1 will show which method is applied to each.
Jacobean Designs. A big selection ol effective designs are obtainable in which conventional llower, leaf and fruit forms are partially worked with tapestry wools in solid embroidery, and partially with outlining and light filling stitches. These designs arc copied and adapted from old Jacobean needle work. Fig. 3 shows a typical corner piece of such conventional form for a cushion or runner, while Fig. 4 gives the outlines to be trunsicred, filling stitches being lelt to the taste of the worker. Suitable transfers are obtainable for cosies and other accessories in this style of embroidery.

Jacobean designs are worked in strong colours, but not too brilliant in tone, as they should look mellowed by age. The large leaf at lower corner of design is first worked in grcen chain stitch and a greenish-blue outline stitch just outside the chain stitch. The veining and stem of leaf, fruit, and Hower are all worked in old gold and brown stem stitch. The small leaf to the right is tilled in with two rows of green herringbone stitch, the stitches lengthening towards the centre of leaf and tapering at point. The sprays of grass at each side of the design are represented by fish-bone stitch, and the round dots are covered with satin stitch, with an outline of black back stitches. The large centre blossom has the four-pointed petals worked in long and short stitch in deep crimson round the tip and a rose-red below.

The other four petals are worked in two shades of greenish-bluc sloping satin stitch, dark blue at the centre of each leaf and medium blue buttonhole stitch all round. with the

stitches about one-eighth of an inch apart. The centre has a cluster of dark-red French knots surrounded with two rows of black chain stitch set square. The solid work at the base of the fruit is carried out in two modium shades of red long and short stitch, while the sides are buttonholed and the centrc tilled in with $\Omega$ couched pattern, such as diamond couching or diaper couching (see page 684), and in cach little division is a French knot. The shades of red used should be intermediate between the crimson and rose-red of the Hower petals. The threc leaves at top of lefthand fruit aro worked in outline stitch, while tho right-band one has the leaves in chain stitch, with fish-bone on the centre veining.

Wool embroidery may be used to ornament woven raffia table-mats or on raflia cloth. Small electric light shades or shields made of linen stretched on wire frames suitable for wall brackets can also be decorated in wool. Care should be taken that the stitchery is neat on the reverse side. Directions for makingup are given ( p . 690) under Lampshade.

medallion is obtained

WORCESTER CHINA. Both useful and type of work box which is useful in a sittingdecorative porcelain lias been produced at roon is the titted box pouffe with a strip for Worcester continuously since the niddle of holding scissors, ctc, and a pincushion attached to the lining of the lid and pockets for reels, skeins of silk and other accessories in the lower part.

In the 18th century a great deal of care and time was spent in producing beautiful workboxes, and some examplesof that period are very fine pieces of craftamanship. Their bcauty was enhanced by the costly woods used for them. Work tables were also made with a receptacle in the shape of a bag under them for holding materials. Such tables wore designed by Sheraton and others and were known as pouch tables. Our illustration shows a work box made the 18th century. Although china figures are in the early part of the 19th century. It is of virtually absent from the range of early wood covered with red morocco and fitted with Worcester, the number of the patterns of tea and coffee services and other useful pieces far excceded that of any contemporary factory in England. In recent years figures and vases have predominated.
The dominant mark until 1793 was the crescent, although down to 1783 many pieces bore a cursive $\mathbf{W}$ and others a square mark some pseudo-Chincse devices, and even the Dreaden croswed-swords. The syuare mark frequently appears on spurious blun-scale Worcester. The second periokl is mostly recog. nizable by the initials or names of the Flights and Barrs, with a crown after 1788. The words Chamberlain's, Worecster, with various devices, serve to identify that factory's out put. Grainger used (i \& Co. in a shield, with Royal China Works, Worcester. The company mark is a crowned circlet enclosing a central creseent or C surrounded by four W's.
Wall's copics of Chinese bluc-and-white, as well as his egg-shell, were supreme. The mugs had vertical sides, and the carly cups usually no handles. Caughley mugs in imitation of Worcester, with a $\mathbf{C}$ sinulating the crescent mark, are recognizable by having splayed instead of straight bases. Vases and jugs with scale-blue grounds have been prized at all times. Hancock's line-engraved prints, which reached their highest level when done on Worcester bodics, were often signed by him, but have no factory mark.
The latter part of the first period coincided with the arrival of artists from Chelsea, and the adoption of marone, canary, apple-green and other grounds, with panels of exotic flowers and birds, or Watteau scenes. There were also wild roses in relief on white, and open-work borders. This carly ware usually contained steatite in the body, and appears greenish when held to the light. The standard English bone porcelain was not established at Worcester until after the year 1840. See China. Worcester Sauce. See Saucc.
WORE BASKET AND BOX. Obtainable in a large variety of shapes and prices, work baskets are made in osier, cane, plaited rush and raffia. Generally they are fitted with the necessary articles used for plain needlework; these are attached directly to the lining, which is provided with pockets to hold cottons, etc.
The large wooden work box fitted with trays and compartments is less in use to-day than some forn of work basket or a work table, which is really a work box on legs. Another forming a small spiral with thr tapered end of a by threading the raffia first round the cane and then carrying it across the cane adjoining, and between it and the one beyond it nearer the centre.
Fig. 3 shows the third round completed, and the commencement of the fourth round. As the work progresses it is necessary to bind the
raffia twicc round the cane in order to cover it in the spaccs between the connecting stitches, which should not be too far apart. Having completed a flat circular mat of the desired size, say 8 in . to 10 in ., for the loottom of the work basket, the cane is continued, but it is placed on the top of the outaide ring instead of on the sides, and continued in the same way, each round being placed on the top of the one below to form the sides of the basket, as in Fig. 4.
Having reached the required height, from 4 in . $t 06$ in., the cane should be sliced to a long taper and gradually worked out so that the top of the sides is llat. A lid is made in the same way as the bottom. and, when the diameter is sufficiently large to fit on top of the sides and slightly overlap them, the end of the canc is tapered and finished off, the raffia being continued for a complete round to give a neat and strong edge. A raffia-eovered ring or bunch of raffia Howers for a handle, or one after the style illustrated on the raffia cosy in page 1035, is secured to the top of the lid, which can be hinged with raffia to the side. The inside of the basket should be lined and padded: if the exterior is to be varnished this should be done before the interior is fitted. The lining niay be of silk or a good printed sateen over a layer of wadding. Separate pockets may be added for recls, tapes, needles and buttons.

Wool embroidery can be effectively used to ornament the cheap rush baskets sold for shopping bags The hand!e is removed and the basket, when em broidered, is lined with sateen. allowing sufficient depth of material to draw up into bag shape at the top after a slot has been made in the sateen to take a ribbon or cord. Buttonhole the lining to the top of the rush basket to keep both together neatly. Any bold flower design may be worked cffectively in bright, rather coarse wools.

A rush or cane waste paper basket makes an excellent mending basket, lined in the same way with $n$ bag top and trimmed with raffia flowers, wool embroidery or appliqué of linen. felt or cretonne flowers

Two complete rounds are formed, Mending; Needlework; Osier: Raffia Work; and then the work is continued, as in Fig. 2, Rush Work; Scissors; Woolwork.

## WOREMISN'S COMPENSATION.

 All householders should insure against liability to pay workmen's compensation to scrvants. The term servants includes not only those who are emploved permanently in and about the household, but also anyone who has regular engagement, e.g. the washerwoman who cones
once a week. There is no liability towards " merely casual person employed otherwise than in the way of the employer's trade.

The amount of compensation payable depends upon the remuneration of the servant. Tips and any board supplied are taken into account. The compensation is 50 per cent of the remuneration for total incapacity with a maximum of 30 s . a week, and a smaller sum fixed either by agreement or by the count. v court judge for partial incapacity : but there are certain percentages which are to be added in the case of both total and partial incapacity where the half wages do not amount to 258 . a week. If a servant is injured or makes a clain for compensation, the employer should at once forward it to the insurance company, and should take great care not to make any admissions which can be used by the servant in support of his or her case should it come into court. See Employers' Liability.

WORKSHOP. The hone worker may be confronted with the problem of finding a place wherein he can do his work with some measure of convenience. He will need a shed or room where he can work at odd moments and, more important still, where his partly completed job can be left in safety. A bench is a necessity, and unless one of the collapsible structures is used, this demands a room or building set aside for its accommodation. Work which has been glued up must be left to set and harden in a place where it will not be interfered with, or be subject to chance knocks. Tools must be housed where they are out of the way of children.

Of course, a sectional building of some sort, as illustrated under the heading Shed, can be purchased, but the home worker will derive pleasure, experience and profit from making his own workshop. Those who decide to follow this latter course could well use a lean-to construction, built into the corner of two walls, as illustrated and described on page 1141.

Much helpful information about the framing, joints, ctc., will be found in such other articles of our Encyclopedia as Garage : Roof: etc., and, of course, the appropriate woodworking contributions can he referred to.

WORM: In Furnitwre. Old lurniture is sery liable to attack by the wondworm, a tiny insect that burrows into the material. Beech, birch and walnut are, perhaps, the most liable to attack, but it is also found in mahogany and other hardwoods.

A good remedy for the worm is a 40 per cent solution of formalin injected into the holes with a small glass syringe. Paraffin is also used and there are a number of patent preparations. Another remedy is to swab the worm-caten wood with perchloride of mercury or corrosive sublimate. This deadly poison must not be allowed to come into contact with the skin. Other remedies include aiternative applications of carbolic acid and paraffin applied to the bucks of wardmber, the insides of chests of drawers, and other places where any ill effects from the acid will not be noticed. Another recommended remedy is paraffin and thymol.
liunligation is another preventive method. Carbon bisulphide is a good furnigant. One way of using this, only suitable, however, for small ficces, is to make an airtight box. to put the article inside this, and to leave it exposed to the fumes for two or three days. The whole surface of the piece is then painted over with a solution of sodium arsennte, a poison which prevents the insects from entering again.

Iarge pieces of furniture, such as sideboards and wardrobee, can be funnigated iuside a tent made of closely woven cotton sluceting, the porousness of which can be reduced by applying to it a linseed oil varnish. Sce Furniture Beetle.

with moss, and the Howers are secured through this to the framework by means of stub wires, which pierec the blossoms.
A withered wreath may be renewed by removing flowers and moss, packing the framework with fresh moss over which trails of cvergreens may be secured with fine reel wire. On one side a bunch of flowers and fuliage can be arranged. If Howers with firm stalks, such as dafforils, hyacinths, carnations, or chrysanthemums, are chosen stub wiring will not be needed. The bouquet can be
WORM : In the Garden. Worms do good arranged and secured to the wreath with wire. by acrating the soil of garden beds and borders, and their preauce shou!d be regarlerl as bencficial. On lawns, however, their casts are a nuisance, disfiguring the grass and giving it a dull, muddy appearance. They can be destroyed by purchasing a worm killer powder from seedsmen.

WORMS : In Human Beings. A great variety of worms infest human beings and domestic and other animals, as well as birds. Intestinal worms aro found in children far more frequently than in adults, and cspecially in weakly children. Parasitic worms come from many sources: thus one species of tapeworm is swallowed in measly pork.

For the prevention of worm infestation, people should avoid underdone or raw meat, water whose purity is doublful, and raw vegetables. particularly watercress, unless beyond suspicion. Intestinal worms are got rid of by means of vermicide drugs, such as oil of male fern and santonin.

WORMWOOD. This is an attractive herbaceous plant or sinall shrub which has fragrant foliage. It prefers light soil and a sunny place. Tlie favourite kind is the southernwood or Old Man (Artemisia abrotanum), 2-3 ft. high, with grey, scented leavea and yellow flowers in summer; it is a common plant in cottage gardens. Artemisia absinthium is the wormwood and dracunculoides is the tarragon. Lactiflora is an excellent plant for the herbaceous border; it grows 4-5 ft. high and bears cream-white flowers in September. Stelleriana, which has grey-white leavcs and yellow flowers, is a trailing plant suitable for the rock garden.

Worsted. See Wool.
Wound. See Antiseptic ; Banaage; Blceding; Cut; Dressing; First Aid: Shock; Tourniquet.

WREATR. Funeral or commemoration wreaths are composed generally of natural Howers and foliage. Occasionally everlasting Howers are used, or a mixture of artificial flowers such as Flanders poppies with evergreens, or a wreath is carricd out in porcelain. A special wire foundation is used in the making of thoral wreaths. It is packed

Wringer. Combinod table and rubber wringer. The reeiliont rollers squeese out moistare efrciently, and at the same time break no buttons or festoners Ewbank Rubber Wringer and Table

Sometimes a bow of ribbon is used to finish off the wreath, or to add a touch of colour to a laurel or palm wreath. The latter are sometimes silvered with metallic paint.

An Easter commemoration wreath may be made on a stout wirc ring, bound round with strips of green crepe paper to which palm leaves are wired; a trimming is provided by a bunch of Howering willow, fir concs on twigs, and purple ribbon artistically arranged. Christmas wreaths of holly can be made in the same manner and completed by bunches of mistletoe and scarlet ribbon.

Wreath designs are popular in all forms of decorative art. Success depends on a sense of balance and colour. Wreaths are composed of every kind of artificial Hower, lcaves and many fruits: and are carried out in appliqué, leather, raffia, ribbon, barbolą and woolwork.

WRENCE. The form of lever known as a wrench is made in many patterns. The screw wrench or adjustable spanner employed to turn a nut on a bolt varics in size from 8 in . to 18 in . and upward, and is either made entirely of steel or fitted with a wooden handle.

Pipo wrenches are made in several forms, the simplest being siniilar to a Hat spanner, but provided with a V-shaped opening with serrated edges. For heavy work the form in general use is composed of a stout handle with a curved and scrrated end, to which is attached a movable clip of circular form. Similar wrenches ano made for use with large tubing.
Tap wrenches for operating serew taps are generally provided with two square holes: the smaller sizes have holes differing by It in., and the larger ones by $\frac{1}{}$ in., and in some cases there are four holes varying in size. There is also an adjustable form in which a pinching serew is turned to closo up the aperture and grip the shank of the tap in use. See Nut; Pipe; Spanner; Stocks and Dics; also illus. above.

WRINGER. This is an inst rument made for forcing water out of wet clothes during laundering operations. It is practically the same as the one known as the mangle, although, strictly speaking, there are slight differences bet ween the two.

The wringer proper docs not roll out the garments or articles washed, as the mangle docs. There are comhined wringers and mangles obtainable, and also washing machines with wringers attacherd.
leollers of rubber am desirable one adran tage of this materinl locing that it is less likely than wood to brata the buttons of the garments. A model of the type illustrated is casy to use for heavy washing, being perfectly rigid and at the amme time constructed to denl gently with light articles. It is convertible into a table.

A smaller type of rubber wringer is manufactured which can be kept on a shelf. A patent reversible drain kecps all water from the lloor, and the machine possesses an attachment which conrerts it into n table mangle. Special littings are made for sink. draining hoard and hath. large wring. ers, like mangles, can be driven clec trically This saving of labour is often cconomically justilied where there is a great deal of home laundering.

A wringcr, whether electrically or hand operatedl, not only en ves time and labour, butalao wrings out the moisture more effectirely than could be done without its aid, and thus enables the clothes to Iry more quickly. Wringers need no ajecial care to lieep them in goodcondition, hut, to avoid straining the rollers, thick materials aliould be folded only once or twice hefore passing through. See Laundry; Mangle; Washer.

WRIST. The the hand and forcarm, contains eight amall hones, called the carpal bones, which above form joints with the lower ends of the two forearm lones, the radius and ulna, and below with the five metacarpal bones. The wrist joint is capable of a wide range of morement, and from its position and structure is very liable to sprains. In Colles fracture (q.v.) the whole wrist is more or less dislocnted backwnril.

Dropped Wrist. Loss of power in the muscleas at the hack of the forearm is the cause of dropped wrist; it may follow any injury to the musculo-spinal nerve which supplies the muscles. It may also be due to the piressure of the head of a crutch. Treat. ment is ly support, massage, electricity, cto

WRITING DESK AND TABLE. The name writing desk is employerl sometimes as if synonymous with writing table. The differences between the two, although these are now somewhat obliterated, are that the desk is a sloping piece of furniture, while the table is not, and that the desk is also a receptacle.
The early writing desk was just a plain piece of carpentry made to slope towards the writer and to stand on the top of $n$ table. It was therefore portable, but lost this advantage when someone formed the iden of fitting legs to it and so making it the writing desk of modern times. The space beneath the top rests are panclled as

Writing Desk and Table. Fig. 1. Writing desk in carved oak. dating from the 17th century. Fig. 2. Beautiful Hepplewhite writing table in mabogang, with tambour tod Fig. 1. bl" permisalon of the Director, Vietorla and dbert

Beautiful kneehole walnut early in the other writing tables were decorated in Chinese lacquer. An example of the latter is illustrated in the article on William and Mary Style. From the kncehole table developed the pedestal writing table. Such tables were designed by William Kent, and came into general use ahout 1735 and onwards for libraries. They were enriched by carving, sometimes by gilding and intended for a central position in the ronm. In some cases the pedestals on which

drawers, but actually open as cuphoards.

W'riting tables of the pedeatal type werc made ly Chippendale. Sometimes their angles werc rounded and ocea. sionally they had serpentine fronts. In claborate cxamples engaged columna are seen at the angles. Hepplewhite made writing tables on the lines of the roll-top desk. An example of his work is illustrated in Fig. 2, notable both for the elegance of its line and its compact was utilized as a re- usefulness. Known as tambour writing tables, ceptacle for papers, theso were fitted with n sliding shutter to and the desk was slip down when the article was out of use also a lox; the ex. ## Wrought Iron Work

## The Making of Articles both Decorative and Useful

Other metal working processes are dealt with In our work under the headings Bent Iron Work; Metil Work; Silver Work; Tinplate. See further the entries on the associnted processes employed, e.g. Brazing; Drilling: Forglng; Riveting; Soldering

The manipulation of iron in bar and sheet to make objects of utility and beauty has been superseded by cast iron and machine presswork to a considerable degree. Generally wrought iron work requires the provision of a forge and an anvil as well as a vice, together with suitable hammers, tongs, pliers, and other tools belonging to the metal-worker. Information about forging, together with details of the construction of a simple portable forge, is given in the article Forge.

The particular processes in the manipulation and treatment of wrought iron are forging, welding, flattening, upsetting, bending, cmbossing, impressing, and punching. Forging is done when the iron is heated to a bright red. Welding consists in forging two separate pieces into one when the iron is at white heat. The parts to be joined are cleaned and sprinkled with borax or sal-ammoniac to prevent oxidization. The striking should be light at first and gradually heavier. Flattening consists of lengthening or widening a picce of bar. This is done with the narrow edge of the hammer, and the grooves so wrought are smoothed out with the large end.

Upsetting consists of thickening the bar and is the opposite of flattening. The method is to strike the red-hot iron on the anvil or to hammer the end. Behding can be done cold as well as when the metal is hot; right-angle bends are done over the edge of the anvil or the square part of the beak: while curves are done on the round end of the beak or on a conical mandrel or stake fitted in the vico. Embossing is the process of making bosses by hammering the hot metal into suitable cavities or by using a ball-faced hammer on a piece of hardwood when the metal is cold. Impressing is a means
of arriving at similar shapes by pressure either with the vice or a press. Punching is used for marking points for drilling and cutting as well as for providing decoration.

Welding and Bracing. There are several methods of joining ironwork, welding being the principal and most generally used in large work, but brazing can be carried out with matcrial of small size. Riveting is necessary in places where welding is not practicable.
There are various ways of joining with rivets, the simplest being where two pieces are to be attached, as at Fig. I. In dealing with curves, another method of riveting is shown at Fig. 2, and consists of cutting away sufficient material to allow the second piece to fit flush. Intersections of bars are carried out as shown at Fig. 3; in this case the top piece is shaped, while hot, between two project. ing blocks. A neat method of intersecting is shown at Fig. 4, and consists of filing out half the thickness of each piece, as at A, so that they may fit flush.

The methods followed in passing one bar through another are shown at Figs. 5, 6, 7, and 8. In the first two the metal is punched and widened out cach side; in the latter examples the hole is drilled and filed to take the bar. When several lengths of bar are to be held, the method used (Fig. 9) consists of forming a collar to bind them together. The collar can be of flat bar or half-round, as at Fig. 10 ; a counbination of the two, shown at Fig. 11, is cffected by placing a collar of half-round bar on a wider Hat collar. Round bars are held together with a collar, as at Figs. 12 and 13.
Straight bar can be decorated by simple means by using a file and a punch, as at Fig. 14. An claboration is shown at Fig. 15. Another method suitable for square bar is shown at Fig. 10 ; the angle cuts are made with a three-cornered filo and the curves with a half-round file. Simple twists (Fig. 17) can be done whilo the metal is red hot, by placing one end in the vice and turning it with the tongs. Square bar can also be $t$ wisted, but it is heavier work and requires the help of a screw wrench. Slitting and opening out, as at Fig. 18, is cffective. The simplest method is to cut the rod to the centre from throe sides, upset it to open out, and then twist. It is, however, a difficult operation for the beginner. Interlacings arc fairly simple, as at Fig. 19, but in Fig. 20 the main rod is split and opened out with the ends forged to a knob form.

The spear shape at Fig. 21 is indicative of Hattening and wclding in the casc of the side picces, otherwiso the lower portion would require considerable cutting away. This form of treatment is used with square bar in railings and similar work, and it can be worked out in many different forms. The formation of the volute, at Fig. 22, is termed scrolling, and is one of the main effects obtainable in wrought iron work. It can be done cold or while the metal is hot, either on the anvil or (usually) with a scroll wrench or round a scrolling iron, which enables an even curve to be formed; these are obtainable in several shapes and sizes. The end of the volute can be flattened, as at Fig. 23, or the widened end can be slit and formed into scparate volutes, as at Fig. 24.

A simple piece of work for the beginner in ecrolling is shown at Fig. 25, and consists of a

 it is usual to weld straight lengths and then form the ends to the required shapes. portion of a grill. The curves are made as flowing as possible, and the nim of the designer of a grill should be to fill the space as decoratively as possible without crowding. Spaces should be well balanced, and the riveted joints just sufficient to hold the work together.

As a rule, wrought iron designs should be highly conventional, and suggest strength. A good finish for wrought iron is to heat the metal and then rub on linseed oil: a black Ginish can be obtained by covering thoroughly with linseed oil and burning it off over a fire.

WYANDOTTE. Amongst exhibitors of poultry the Wyandotte is without doubt the most popular of all the American breeds. There are 13 varieties, namely: white, black, blue, buff, Columbian, blue-laced, buff-laced, black-laced, gold-laced, silver-laced, pile, silver-pencilled and partridge. The favourites are the white, black. silver-laced, gold-laced and the Columbian.

Wrandotte. Pullet of the white variety of this Amerioan breed

An example of welding, intersecting, and reu combs, faces, wattles, and lohes. They riveting is shown at Fig. 27 in the form of a are all rose-combed. See Fowl: Poultry.

ERANTEEMUM, This is the name of an annual everlasting flower or :mmortelle which is useful for indoor decorstion in winter. It is grown from seeds sown out of doors in spring. Of this flower the chief kind is Xcranthemum annum, 18 in.

E-RAY: The Rönt gen rays, which are inore commonly known as the X-rays, have some very important uses in diagnosis, and also in the cure or relief of certain diseases. For the purpose of diagnosis, they are employed to reveal the presence and situation of foreign bodies, for fractures, dislocations and for various diseased conditions.

What is shown on a photograph is not the actual object or tissue, but the shadows of theso thrown on the photo. graphic plate. The interpretation of these photographs requires special skill and experience.

Un the cells of the body the rays have a stimulating cffect, which becomes irritating and destructive when the application is prolonged. A large number of affections are successfully treated by X-rays. These include ringworm and many other skin diseases. With regard to cancer, apart from rodent ulcer, X-rays should not be used if an opera. tion is possible; but when it is too late for a successful operation they often give great relief and prolong the life of the patient.

EYLONITE. A manufactured form of celluloid, xylonite is made in various colours and in imitation of ivory, tortoiseshell, etc. It is manufactured in sheets of various thicknesses and can be used for many purposes. Owing to its inflammable nature it should never be placed near a flame nor exposed to heat. See Celluloid.

YACET : How to Make. The design of a model sailing yacht must follow certain definite rules too numerous to include in this short description, but they aro followed in the design shown in the side elevation at Fig. 1. The hull is shaped from a 36 in. by 9 in . by $3 \frac{1}{\mathrm{i}} \mathrm{in}$. block of sound wellseasoned wood planed to the dimensions given, yellow pine, spruce or cedar being suitable.
The first thing to do is to prepare ternplates of the sections indicated by the lines on the deck plạn at Fig. 2, the section at Fig. 3, and the section lines at Fig. 4, the latter being drawn out full size, together with the sheer plan outlined at Fig. 1, and deck plan at Fig. 2. The templates can be of stiff paper, as at Fig. 5, and represent the shape of the hull at intervals of 6 in ., being marked $B, C, D, E$, and $F$. In order to nold the wood securely in the vice, a 2 in . by 2 in . by 12 in . block should be screwed to the top so that the jaws of the vice can grip it and allow the whole of the hall to be worked. The plane, spokeshave and chisel should be used to cut away the waste, and great care must be taken to fit the templates at the correct places, as shown.
The surface, when correctly shaped,-must be thenoughlv smnothed. libet-with a scraper and finally with glaor paper. Tho most suitable wood for tho kcol is beech; it should be prepared to the shape shown from 1 in. board with a length of 25 in . and a depth of 69 in . The lower edges are rounded off to a sharp edge except that purtion at the bottom which is covered with lead. A horizontal groove is now cut along the centro of the hull to a centre depth of $1 \frac{1}{6}$ in., so that the kecl will fit tightly and can be glued in position. The top is now curved with a drop of $\frac{t}{z} \mathrm{in}$. in the centre and the inside of the hull is removed, by boring a number of holes with a large centre bit and then using one or two sizes of firmer gouges; the sides should be left to a thickness of $\frac{1}{\frac{1}{2}} \mathrm{in}$. until the inside is neatly shaped, and in order not to cut down too deep, three or four inside templates should be uscd. The greatest thickness at the bnttom should be $1 \frac{1}{4} \mathrm{in}$. to allow for the depth of the groove; in any case, this should not be less than 1 It in.

When the shaping is finished, a $\frac{A}{A}$ in. linc should be gauged from the top and a $\ddagger$ in. line from the outside to enable the rebate to be cut for the deck; the latter being shaped from in. wood. The keel is now further secured with screws driven in from the inside of the hull and the two lead weights made and screwed to the bottom of the keel. The easiest way of providing the picces of lead is to model the shape with a piece of plasticine and make a plaster of Paris mould; two separatc castings can be made and fastened to the sides of the keel.

An alternative method is to cast the bulb with a groove in the top so that the planed off
ked can be fitted and the lead attached with gaff are threaded through tho gaff side the cap, or hatch uncovered when the yacht screws driven in from the bottom. The at $U$ and $T$ and carried through the first of is not being used. It is advisable to have a approximate weight of the lead should be ll lb. three small cyes at $V$, and secured to the spare set of spars, and the wise yachtsman with several coats of good oil paint, rubbing down the outside coats and finishing with cnamel or carnish. The spars should be made from a close and straight grained wood, and generally pitch pino is used. The mast is 58 in. long, $\frac{1}{8}$ in. diameter at deck level, squared at the bottom to $\frac{1}{2} \mathrm{in}$. side and tapered to in. at the top. The surface should be carefully finished and made perfectly smooth. A block of wood is placed inside for the heel of the mast to fit in, and a hole bored in the deck and surrounded on both sides as at H with a 2 in . by $1 \frac{1}{2} \mathrm{in}$. by $\frac{\mathrm{i}}{\mathrm{in}}$. strip of wood.

The centre of the hole in the deck should he 13 in . from the bow of the boat; the centre of the hole in the block inside should be stepped back to allow a rake of 2 in . in all. However tightly the mast is fitted through the deck it is hardly possible to kecp the inside quite watertight; it is therefor necessary to fit a brass screw cap, as used in gas fitting, at the stern as at K , so that any accumulation of water can be emptied out.
A shallow deck house, composed of a $3 \frac{1}{2}$ in by $2 \frac{1}{2} \mathrm{in}$. by 1 in ., and a $1 \frac{1}{8} \mathrm{in}$. by 1 in . by $\frac{1}{2} \mathrm{in}$ piece of wood glued together, is secured to the deck as shown at 1, in Figs. 1 and 2. Cleats measuring $2 \frac{1}{2} \mathrm{in}$. long and made from $\frac{1}{2} \mathrm{in}$. by $\ddagger$ in. wood are fastened on as at $M, N$, and $P$ but the thickness of the deck is inereased by in. at the bow by a shaped piece glued and bradded to it. The deck can now be nitached to the hull and the remaining spars and rigging completed. The bowsprit is 13 in . long, tapering from $\frac{1}{2} \mathrm{in}$. to in., and secured to the deck by fitting the heel in a serew eye and binding wire round it and fastening to a small screw eye at $Q$. The boom is 26 in . by in. diameter and is attached to the mast by two screw eyes.

The mainsheet is secured to the end, run through a block attained as at R. with n closed S hook to a horse made of wire, and through another block as at S. and then through a serew eyo in front of the horse direct to the cleat at M. The mainsail measures 25 in . at the foot, 31 in. along the leach, 18 in. at the head, and 183 in. along the luff. Three brass rings are slipped on the mast and the sail is then sewn to them.

The gaff is shaped to $\frac{8}{\text { in. by }}$ $\frac{1}{2} \mathrm{in}$. by 20 in . It is provided with small screw cuce, one at the throat, another 8 in., and another 6 in. further on. lt is hold in position ns shown at Fig. 1, the serew cye at T being 21 in . up the mast and those at $U$ being $2 \frac{1}{2} \mathrm{in}$. above. The jincs securing the

The hull should be painted inside and out cleats at $P$ and $N$ respectively. The top. will carry a length of cord, sonce wire and a sail measures 30 in . by 24 in . by 15 in . : it is pair of plicrs, so that repairs can be carried secured to an eyc at the top of the mast, to a out on the spot when urgent. Sce Boat.

YARD : The Measure. The yard is the standard English measure of length. A yard is divided into 3 ft . or 36 in . A square yard contains 9 square feet and a cubic yard contains 27 cubic feet. There are 220 yards in a furlong and 1,760 in a mile ; 4,840 square yards make an acre.

YEAST. Yeast is a plant of the fungus order which is formed in fermenting liquids and plays an important part in brewing and also in baking. Fermentation takes place when yeast is added to sugar, alcohol and carbonic acid gas being given off. Yeast is added to dough in baking in order to make the bread light and porous, the gas causing it to swell up into the consistency of a sponge. A tepid liquid must be used, as yeast is inactive when dry and cold, while too great heat kills it.

Yeast has various uses in medicinc. It is sometimes given to patients suffering from boils, acne, and tuberculosis, as it appears to increase the number of white corpuscles in the blood. The dose is about 2 teaspoonfuls in a little milk once or twice a day. Yeast cells are rich in anti-ncuritic vitanin, as are also extracts of yeast. The latter resemble meat extract in their propertics, and arc used in diet.

Yeast Cake. This cakc is made with 3 lb . flour, 4 oz. each lard, margarine, dricd currants and sultanas, 4 oz. moist sugar, 2 o7. chopped lemon peel, 3 pint each of milk and water, $\frac{1}{2}$ oz. ycast, a littlo brown sugar and a pinch of salt. Put the flour inte a basin, add the salt, and rub in the lard and mar. garinc. Put in the fruit, sugar and peel, mix the yeast with a little warm water and brown sugar, pour this into the centre of the mixture and leave it for 10 min . Then pour in the milk and water and beat all well together. Put
it in a warm place to rise for 2 hours, and then bake it in a hot oven.
YEW. This is a most valuable evergreen suitable for hedges, for planting as specimen trees on the lawn and for topiary work, for it bears clipping well. It flourishes in ordinary soil that is not water. logged. The common yew is Taxus baccata: it lives to a great age1,000 years or more.
The branches and leaves, especially when withered, are poisonous to cattle.
lew is largely planted as a hedge though it grows slowly for the first few years. The Irish yow (Taxus bacYachl. Fig. 1. Side elovation of a model asiling yachh which can be made by the amateur by follomine the cata fastigiata) inatructions given in the tert. Pig. 2. Plan of deck. Fig. 8. Sectional view of yazht. Fig. 4. Seetion lines of
evergreen tree of upright conical habit of growth and is often planted on lawns; the variety aurca has golden ycllow leaves. The yow named Douastonii is of graceful drooping growth. The best time to transplant yew trees is in May or September.

Yew trees ought to be clipped carly in May and again in Allgust. If an old, overgrown hedge has to be cut back the work should be done in April.

Uses of the Wood. This wood is very hard and lasting. Susceptible of a high polish, it is insect proof. It is not greatly used for furniture to-day, but is sometimes employed for marquetry. See Hedge : Topiary.

YOGHOURT. Curdlel milk has long been largely used in the diet of many countries in south-castern Europe. The best known pre paration is Bulgarian yoghourt or yohourth, in which the souring is produced by the bacillus named bacillus llulgaricus. Metehnikoff suggested the use of this preparation in the treat. ment of disease, the acclinatisation of the Bulgarian bacillus lessening intestinal putrefaction. Nince its introduction this method of treat. ment has attained high popularity, and it has been recommended in cases of chronic ill-hcalth without obvious cause. neurasthenia, and certain intestinal affections such as colitis, diarrhoea and constipation. See Sour Milk.

YORESEIRE PUDDING. There are sercial methods of preparing this batter, which is a usual accompaniment of hot roast beef. The tin or dish must be prepared by melting in it plenty of good dripping, which should be well heated before the batter is poured into it. Before serving, the pudding should be turned out and cut into neat pieces, which are arranged on a hot dish. For an economical Yorkshire pudding sift 8 oz . Hour with $\frac{1}{2}$ teaspoonful salt into a basin, make a well in the centre and break in two rgga. Beat these with a portion of Hour till light. Then add by degrees 1 pint milk and water. beating all the while. Jet the batter stand I hour. then pour it into a heated and greased tin. It should be baked 30 to 40 minutes.

Occasionally the pudding is cooked in the same tin in which a joint is being baked. If eo, the meat must be raised on a trivet and the batter should not be poured in until the meat has been partly cooked. The ohjection to this tuethod is that much of the gravy

Yorkehire Terrier. Champion of this long and zilkyhaired breed of toy dos
and dripping from the nicat is absorbed hy the batler. A portion of dripping may bo poured of before batter is put in. See Batter.

YORESHIRE TERRIER. This is the name of a pretty little loy dog. It possesses a vigorous and well-proportioncd body, and carries it eompletely hidden bencath the close straight veils of silky hair that fall from the parting along the middle of the back to the ground on cither side. The coat should be uniformly of a bright sterl bluc without a fawn or tan hair : but the long and abundant hair on the head cars and under the chin should be tan. The nose should be perfectly black. See Dog ; Terrier.

YUCCA. This is an evergreen shrub of triking appcarance with long leaves and upright panicles of white or cream white flowers. They like well drained soil and are propagated by offsetes in spring: these are taken off the old plants, potted and kept in a frame until rooted. Yuccas flourish in town as well as in country gardens. The favourite kind ir Adam's ncedle (yueca gloriosa), which has stiff leaves and an immense spike of bloon. Yucer recurvifolia and yucca filamentosa, the latter almost stemlers, arc among the other kinds.

Zinnia. Gaily coloured blossoms again becomes brittle. Soldering.
brittle, but it is mallcable when heater to a temperature between $100^{\circ} \mathrm{C}$. and $150^{\circ} \mathrm{C}$.; when it is heated abovo that temperature it

Zinc is scarcely affected by dry air ; in damp air the exposed surface is converted into a basic carbonate of zinc, owing to the presence of carbonic acid gas, and this effectively protects the metal from further changc. On account of this property zinc is employed for rooting and also for tanks. It is used to a much greater extent in "galvanizing" iron andl stecl; the metal is cleaned with acid to remove the scale, and is dipped into the molten zine. The result is to protect the iron, which is quickly oxidized by exposure to air and water, and provides a rustless surface. See I3oat; I)utch Metal; German Silver; Ice Nafe; Ormolu.

Medicinal Uses. Numerous compounds of zinc are used in medicine. Zinc chloride is a powerful caustic, and at one time was commonly used as an antiseptic. The acctate carbonate, oxide, and sulphate of zinc all act as astringents when applied to raw or ulecrated surfaces, and are therefore often of valuc in solution as astringent lotions. Lotions of zine sulphate or other zinc salts provide the best remedy for one form of conjunctivitis.
Powdered oxide of zinc and powdered cartonate of zinc are commonly used as dusting powders where a mild astringent effect is required. Calamine ointment, much used in skin diseases, is made with native zinc carbonate, otherwisc known as calamine. Interually, zinc sulphate is a prompt and valuable emetic in certain cases of prisoning.

ZanNLA. The zinnia is a half-hardy annual bearing flower of rich colours, some of double form, including crimson, scarlet, bronze, white, buff. violet, and mauve. The plant is prolific and long. lasting, but demands all the sunshinc possible and well. enriched soil. Sced should be sown in heat during March, transplanting sced. lings once or twice to makic good stocky plants.

ZITHBK. As a stringerl instrument the zither stands in a class by itself, for the strings are plucked both with the. fingers and with a plictrum. It consists of a wooden body, about 1 ft .

ZEPHYR CLOTA. Zephyr cloth is a 8 in . long, 10 in . wide, and 3 in . dcep, which, cotton fabric somewhat resembling when played, is placed upon a table. Ufo: gingham in texture, and of light or the side farthest from the performer the medium weight; it usually contains two or body has a very pronounced bulge beyond more colours, woven in a variety of patterns. the strings, the object being to increase ZINC. A bluish-white metal, zinc is harder the resonance of the instrument. In the than aluminium and softer than silver. It is upper table of the body there is a large, stronger than lead or tin, and has a bright circular sound-hole. The 30 strings, which run lustre when polished. Being mallcable, it can from left to right, fall into thrce distinct be hammered and rolled into thin sheets. classes, namely, the melody, the accompaniCommercial zinc, which is called spelter, is ment, and the bass strings.
